References in some recent South American constitutions to “right of nature” have been rhetorical, at best aspirational and without tangible effect in dealing with governments that are focused on economic development or movement of impoverished urban residents to locations traditionally occupied by indigenous people (Boyd 2017; Colón-Ríos 2015). Recognition of rivers in Bangladesh and elsewhere as “living entities” does not give those domains legal agency (Islam and O’Donnell 2020; Jolly and Menon 2021). In

terms of a politics of sustainable management is akin to statements by governments in the Global South about their commitment to human rights, either disingenuous or a manifestation of state incapacity (Wesche 2021).

Summary

Personhood underpins notions of sustainable management of human, natural, and other resources. It is a legal mechanism that for many people is so prevalent as to be unremarkable, even unrecognized. As a legal mechanism, it is protean: it can be expanded, restricted, and reshaped according to social needs and the persuasiveness of particular stakeholders (e.g., oil, gas, and coal corporations) whose perceptions of sustainability may be founded on special interests. Disagreements among theorists exacerbate popular misunderstandings about new personhoods (e.g., for specific rivers and mountains) and assertions that “nature” has legal rights that should determine decision-making by legislatures, courts, regulatory agencies, and businesses.

Definition

Phenomenon-based learning (PhBL) is an indistinct concept with many roots. Its unclear principles are interpreted and implemented in many ways. It is neither a theory nor a method, but it is called an approach. PhBL relates to a pedagogical way of viewing learners, teachers, and knowledge of the world both distinctly and in their context.

PhBL has been shallowly investigated from a theoretical perspective, and the methods by which it is implemented vary. Theoretically the concept is based on constructivism, pragmatism, and phenomenology. Politically the concept connects to transversal knowledge and twenty-first century skills. Methodically it relates to problem-based learning (PBL), inquiry-based learning (IBL), phenomenological learning, hermeneutic learning, et cetera. Among the core features of PhBL are that it is interdisciplinary (see ► [“Transdisciplinary Learning”](#)), student-centered, collaborative, and build on authentic problems. In psychological perspectives, learning is linked to the students’ interests and emotions (Lonka 2018). Philosophical perspectives emphasize comprehensive learning situations and seeking answers on ethical and existential questions (Küpers 2012). PhBL takes place in early childhood settings, schools, and in higher education. It relates to phenomenon-based research used in management and organization science (von Krogh et al. 2012), and has been proposed as one answer, even if not the only one, on how to meet the educational challenges of sustainability (see ► [“Sustainable Development,”](#) and ► [“Sustainable Education”](#)) (Vlieghe and Zamojski 2020; Wolff et al. 2019). PhBL is thus future oriented, and at its best, it is a transformative prospect (see ► [“Transformative Learning”](#)).

Introduction

Phenomenon-based learning (PhBL) is a learning approach rejecting a subject-based and information-driven view of education. In PhBL, the emphasis is on entreties that are unified from several angles. The starting point is an apparent phenomenon, even if intangible (Lonka et al. 2015), and the learners are viewed as curious and dynamic participants in their own learning. Therefore, the focus is more on experiences and actions than on obtaining information. Yet, the phenomenon-based learning process includes theoretical knowledge, and is a continuous shift between theoretical studies and hands-on activities (see Dewey 1930; Wolff et al. 2019). The student is recognized as a social being who

receives a broader view of the topic of study in a social learning process than alone (see Bruner 1997; Dewey 2009). Finland, a successful country in international educational assessments (e.g., PISA, Programme for International Student Assessment), has been noted as the country that initiated the PhBL approach. However, this is a simplified picture. To explain the background, some basic concepts are crucial.

The “phenomenon-based learning” concept includes two intricate notions or separate concepts: “phenomenon” and “learning.” Like many other words, phenomenon occurs both in everyday language and as a scholarly concept. According to the Cambridge Dictionary (2021), a phenomenon is “something that exists and can be seen, felt, tasted, etc., especially something unusual or interesting.” The Oxford English Dictionary (2021) describes phenomenon as “[a] thing which appears, or which is perceived or observed; a particular (kind of) fact, occurrence, or change as perceived through the senses or known intellectually; esp. a fact or occurrence, the cause or explanation of which is in question.” The second of these interpretations comes closer to a philosophical explanation that perceives phenomena as more than tangible objects.

As a scholarly concept, phenomenon has a fundamental position in phenomenology. The main initiators of phenomenology are Edmund Husserl, Martin Heidegger, Jean-Paul Sartre, and Maurice Merleau-Ponty (e.g., Smith 2013; Østergaard et al. 2008). Phenomenology was central in the continental European philosophy throughout the twentieth century and it has developed in many directions. Even if Husserl is often called the father of phenomenology, Kant’s philosophy and his call for a return to “the thing in itself” (*das Ding an sich*) is a foundation of phenomenology. With the things in themselves, Kant meant the forms of ideas and contents of lived experiences (see Carman 2014).

Phenomenology addresses the meaning things have in human experiences, in their “life-world.” Such things may be objects like tools, events, the flow of time, or oneself and other persons (Smith 2013). Meaning thus entails the intuitive

soundness things (phenomena) have when somebody confronts them in practical situations. However, phenomenology is not only subjective, limited to one single personal perspective. It is a joining of a person’s own previous experiences with other persons’ experiences (intersubjective) that pays the way to both individual and interpersonal reflection and judgments. An aim is to understand the world from many perspectives, like politics, religion, and economy, and realize how these positions have changed and influenced society historically (Merleau-Ponty 2014). Accordingly, learning occurs in many ways and through diverse forms of media (Küpers 2012).

The other main concept in PhBL, “learning,” relates to education, and takes place during human life in most contexts (Jeronen 2012; Wolff 2011). It has been the topic of discussion and development since the earliest times. Even if learning is the aim in various educational circumstances and environments (see Sewell and Newman 2014), learning does not always come about (Biesta 2020; Wolff 2011). For learning to be successful, many fundamentals must coincide. In phenomenology, learning is about going back to learning itself, and the living process of learning, in which the embodies learners meet, co-create, and mediate what they have bodily learnt (Küpers 2012; Merleau-Ponty 2014). When education is at its best, it can even advance towards “transformation” of the learners’ thinking or practice (see ► “Transformative Learning”). In the contemporary world with its huge and complex dilemmas of unsustainability, climate change (see ► “Climate Change”), biodiversity loss (see ► “Biodiversity” and ► “Biodiversity Education”), and a challenging pandemic, the voices arguing about what future education and learning might be, has become louder (see ► “Decade of Education for Sustainable Development”, ► “Sustainable Education”, and ► “Education for Sustainable Environment”). Therefore, successful sustainability learning is more than being present in a learning situation or remembering content; it is about reflecting on various perspectives and being willing to participate in the joint shaping of a better future.

Two Concepts: Bildung and Constructivism

A brief explanation of two additional concepts, “Bildung” and “constructivism,” is necessary to make the PhBL approach intelligible. The “Bildung” concept emerged among German speaking philosophers at the end of the eighteenth century (Horlacher 2015). It originates in the Greek concept “paideia” (or paideia) that describes an ideal education. The Bildung concept is complex and difficult to interpret, and it has no straight translation in English. It describes a transformation (often metaphorically compared with a journey) that engages the individuals at a personal level as well as in their social interactions with others (see Wolff 2007). Bildung is not only an educational idea that concerns individuals; it is strongly connected to social and political matters like values. Moreover, Bildung is distinct from an education, which only involves adaption to given conditions and learning in the sense of gaining factual knowledge (Horlacher 2015). Conversely, it entails that somebody has a broad view of knowledge, understands complexities and connections, and is able to reflect on one’s own learning in a meta-perspective (Burman 2009). Accordingly, the aim of Bildung is more than a personal transformation; its aim is to prepare the individuals so they can change the entire society (Horlacher 2015). In a neoliberal educational context, an ideal education with an open-end like Bildung has been sidestepped by competence thinking focused on quality-control and measurable outcomes (Schaffar 2021). (Concepts similar to Bildung are the African “Ubuntu,” see ► “Ubuntu,” and “the American Liberal Education,” see Nussbaum 1998.)

“Constructivism” is both a theory on the nature of reality (ontology) and a theory of knowledge (epistemology). According to constructivism, human knowledge is based on experiences, mental structures, and beliefs, which with new information construct meaning and understanding (Göğüş 2012). Consequently, learning means constructing understanding by reflection on earlier experiences. Among the constructivist

approaches are cognitive/personal constructivism, social constructivism, radical constructivism, critical constructivism, and cultural constructivism. Significant theorists who have influenced the constructivism approaches are Jean Piaget, Lev Vygotsky, and John Dewey. Compared to phenomenology, which emphasizes a precognitive and sensitive phase, constructivism focuses more strongly on cognition and constructing knowledge (Østergaard et al. 2008). In opposition to Piaget and the constructivist view, Merleau-Ponty (2014, see also sections “[Introduction](#)” above and “[Phenomenology and Phenomenon-Based Learning in Science Education](#)” below) regards the bodily perception of the world as prior to the intellectual awareness. Thus, persons see, hear, and smell before they can think about a phenomenon.

Phenomenon-Based Learning in the Finnish Curricula

The PhBL concept is strongly related to the Finnish educational context. Many times, especially on contemporary social media, PhBL is regarded as something typically Finnish. Undeniably, the Finnish core curricula from the 2010s have a focus on phenomena and emphasize holistic approaches. Numerous experts from various educational fields, politics, and business have been involved in the compilation of the Finnish curricula. Therefore, the comprehensive and phenomenon focuses are based on many divergent roots. One is Bildung, another is constructivism, and a third is the idea of core competencies, which relates to the “twenty-first century skills” political concept. In addition, there is an obvious future orientation.

The Finnish *National Core Curriculum for Basic Education* (students aged 7–15) (Finnish National Board of Education 2014), as well as the *National Core Curriculum for General Upper Secondary Education* (students aged 16–19) (Finnish National Agency for Education 2019) have a strong focus on comprehensive approaches. The documents ambiguously express a cross-curricular attempt in many ways, for

example, by using the concepts “transversal competence,” “crosscutting competence,” “integrative instruction,” “holistic approach,” and “multi-disciplinary learning.” Yet, a comprehensive approach is nothing novel in the Finnish educational history; an integrated curriculum has been the issue many times. The first wave came at the beginning of the twentieth century, the second in the 1930s, the third in the 1970s, and the fourth in the 1980s (Niemelä 2019). In the 1990s, Maijaliisa Rauste-von Wright and von Wright (1996) were among those who wrote about the problem with curricula that split the learning contents.

The word phenomenon is used frequently in the Finnish curricula, even if the entire concept of phenomenon-based learning is rare. The word phenomenon mostly occurs as an ordinary word (see section “[Introduction](#)”). The English version of the curriculum for basic education uses the “phenomenon-based approach” and “phenomenon-based method” formulations (Finnish National Board of Education 2016). However, the PhBL approach is nothing new either. Rauste-von Wright started the development of phenomenon-based learning in a Finnish teacher education context by implementing the philosophy of Dewey and of Georg Herbert Mead, unifying their theories into a pragmatic form of constructivism. She saw the development of the human mind as a result of humans’ interaction with the natural and social environments (Lonka 2018). Particularly Kirsti Lonka, Lasse Lipponen, and Kai Hakkarainen continued Rauste-von Wright’s PhBL development and included ideas from inquiry-based learning (IBL) in the PhBL approach (Lonka 2018). (Read more about IBL in Caliskan 2012.)

Following the constructivist psychology ideas, Rauste-von Wright et al. (2003) saw students as being active learners who reflect and construct knowledge when they confront new experiences. Consequently, Lonka et al. (2015) recommend that the PhBL process starts from a mapping of the students’ pre-understanding. Based on Vygotsky’s and Jerome Bruner’s theories, the learning process takes place in collaborative learning situations. The approach is interdisciplinary and may include experts from various fields.

According to Symeonidis and Schwarz (2016), the focus on phenomenon in the Finnish curricula is based on reform pedagogical approaches to teaching and learning neglecting more complex educational situations. In addition, it relates to politics and economy. The Finnish curricula work situated the PhBL idea in the OECD political context (Niemelä 2019). In the curricula, PhBL clearly is connected with transversal knowledge, which relates to EU politics (see also Halinen and Jääskeläinen 2015). In the EU view, “transversal knowledge, skills and competences (sic) are relevant to a broad range of occupations and economic sectors” (EC 2000). These skills are often referred to as core skills, basic skills, or soft skills, the cornerstone in a person’s development. Transversal knowledge, skills, and competencies are the building blocks for the development of the “hard” skills and competence required to succeed on the labor market. The transversal knowledge, skills, and competencies are organized hierarchically: Thinking, language, application of knowledge, social interaction, and attitudes and values (EC 2020). Correspondingly to the EU politics, the Finnish National Core Curriculum for Basic Education includes seven transversal competence areas. They are (1) thinking and learning to learn, (2) cultural competence, interaction, and self-expression, (3) taking care of oneself and managing daily life, (4) multiliteracy, (5) ICT competence, (6) working life competence [employee competence] and entrepreneurship, and (7) participation, involvement, and building a sustainable future (Finnish National Board of Education 2016, pp. 47–58).

Likewise, PhBL has connections to the twenty-first century skills (Lonka 2018), and they are also of strong political interest. The World Economic Forum (WEF 2016) regards collaboration, communication, and problem-solving as the most important future skills beside traditional academic learning. However, the WEF’s instrumental aims are not in line with an open-ended Bildung process with a long tradition in Finnish education (see Wolff 2007). In the curricula, Bildung has lost many of its basic ideas and is blended with contrasting aims. However, it is common that national curricula are syntheses of different

imaginaries and connect to global economy and labor market interests (Zilliacus and Wolff 2021).

The Phenomenology of Learning

There are also educational views associated with collaborative learning and phenomena in education other than the Finnish described in the previous section. According to phenomenology, the learning from phenomena is considered from an angle other than through constructivism. In phenomenology, education is an existential human project with an interest in human life and meaning making. It is a dialogue that never ends, and “an ongoing commitment and responsible attention to human life and its concerns” (Biesta 2020, p. 12). Wendelin Küpers (2012) uses the concept of “phenomenology of learning” as a synonym to a “phenomenological approach to learning,” “embodied learning” and “experiential learning.” He is critical to education endeavors that quantify, itemize, and control. Instead, he defines learning according to phenomenology as an “embodied, emotional, cognitive and responsive, individual and/or collective accomplishment, and dynamic process” (p. 2611). Besides acquiring knowledge, learning is a way to make sense of oneself, others, and the world in a transformational process:

[L]earning creates, captures, transfers, and mobilizes as well as modifies not only knowledge of and between individuals and on a collective level, but also transforms the learner... (Küpers 2012, p. 2611)

In this process of being and becoming, learning has a sensual and embodied dimension, as well as a linguistic dimension. The learners are encouraged to become ethically reflective (see ► “Ethics”, ► “Ethics and Ethical Theories”, ► “Ethics of Sustainability Education”, and ► “Phronesis”) and restructure their earlier assumptions about humanity, democracy, and political agency (see ► “Agency Theory”) (Küpers 2012). Küpers (2008) has also developed thoughts on how to implement the phenomenology of learning at an organizational level to overcome a reductionist orientation, and promote a multidimensional and inclusive approach of the lived experience.

Phenomenology and Phenomenon-Based Learning in Science Education

Since the 1970s, science education has endorsed phenomenology. The phenomenological endeavor is a critique of science lessons that are too abstract, laboratorial, technical, and mathematical. Instead of learning, which separates the students from their own experiences, the effort is on inclusion of the students in the learning process (Østergaard et al. 2008). Francis et al. (2013) describe a Norwegian PhBL university course included in a phenomenology-based program in agro-ecology. In 2000, the developers of this course started to use a PhBL approach. They tried to shape a whole picture of a complex issue through a combination of biophysical, economic, and social methods training the students in transdisciplinary and responsible actions.

Just as farming and food systems need to be resilient and sustainable in the long term, the learners themselves as well as their instructors need a capacity for continuous renewal and growth. (Francis et al. 2013, p. 64)

In agreement with a traditional *Bildung* idea, the course uses an “open-ended case strategy,” which means that the teachers do not have a fixed answer on the question the students explore. Instead, students, teachers and other stakeholders collaborate and search to develop several future scenarios towards “action-based knowledge,” that is, knowledge that emerges in a process including both theories and practice. Consequently, along with the phenomenological thoughts of Merleau-Ponty (2014), experiences precede the theoretical knowledge. Yet, both theories and practice are important for learning.

Following Merleau-Ponty (2014), the human relation to nature is not knowing, but doing (Østergaard et al. 2008), since perception is both bodily and intentional. Perception comes first, which is a critique against the Cartesian expression “*Cogito ergo sum*” (I think, therefore I am).

I cannot enclose myself within the universe of science. Everything that I know about the world, even through science, I know from a perspective that is my own or from an experience of the world within

which scientific symbols would be meaningless. (Merleau-Ponty 2014, p. lxxii)

Not all attempts to use phenomenology in science education are PhBL, but there are similar didactic elements. Like Edvin Østergaard, Wolff-Michael Roth (e.g., 2016) has applied Merleau-Ponty's embodiment ideas, but also the ideas of others, like Baruch Spinoza and Dewey, in his science education research. Roth has studied the importance of emotions in learning situations. He asks for mathematics education that nurtures astonishment and passion (Roth 2017). This implies a negative risk of vulnerability, but also a positive sense of wonder, gratitude, and excitement. In a perspective that is broader than a single subject, it is about nourishing "a culture of astonishment" (Roth 2017, p. 98). Astonishment can thus become a boundary transgression releasing a new intellectual horizon and open the students' eyes for the beauty of the subject or phenomena (cf. Vygotsky 1978). Sungwon Hwang and Roth (2008) have problematized how a student can learn about an issue or content that initially is foreign or strange. In addition, they examined what emotions confrontations with the strange may initiate. Their study shows that the living body is central in a learning situation including something strange, and that empathy is fundamental to learning science. However, even if emotions are important in sustainability education in a situation when climate change threats are steadily increasing (Pihkala 2020), education also must build the grounds for how to confront the future from an ethical viewpoint.

Phenomenon-Based Learning Towards Sustainability

Since 2017, a Finnish interventional research project has focused on the development of sustainability education for student teachers in a World Heritage center through a PhBL approach (Wolff et al. 2019). In this project, the researchers employ various phenomenology-based approaches, especially the phenomenology of Merleau-Ponty, but they are also influenced by Vygotsky, Dewey, Mezirow, and others. Another phenomenology-

related foundation is Bildung theories. As a third base of this project is various sustainability education approaches. Embodiment and arts are important elements, likewise the encouragement of the student to self-reflection (Taylor 2009). Learning takes place outdoors in an authentic world heritage environment. Authentic learning grounded on situated approaches in real-world contexts is beneficial for learning (Herrington and Herrington 2006). In this project, a combination of local (urban) and global matters challenges the learners from historical, present day, and future perspectives (see Wolff 2011). Even if it is delicate, the project tries to face sustainability in all its challenging complexity, jointly comprising ecological, social, cultural, and economic dimensions.

The aim of the project is both transdisciplinary and transformative learning processes, and the role of language and multilingual expressions are important (Wolff et al. 2019). The first pilot course experimented with phenomena in the form of word pairs like "children and peace," "we and they," "light and shadow," "words and power." The students' reflections advanced from tangible ideas to more and more abstract and symbolic spheres and the students managed to exceed the subject limits. The PhBL process led to reflections on social sustainability topics like identities, ideologies, discrimination, and inequality (Wolff et al. 2019).

The project consists of nine researchers/lecturers from a range of teaching subjects, in addition to several student researchers. They all contribute with their specific knowledge background in a co-teaching experiment. During the Covid-19 in 2021, trials with inclusion of many experts from outside the learning context as lecturers and improvisators, like dancers were carried out as part of this project. They also used digital storytelling as a method to implement the phenomenon-based learning process (see Blomberg 2021). The outcome of this last course experiment is still under scrutiny.

Summary

Many foreign websites describing phenomenon-based learning in Finland maintain that the

Finnish schools have given up the subject orientation (see Lonka 2018), but this is not the case. PhBL is no replacement for subject learning, and it is not even suitable for all learning topics (Lonka et al. 2015). When learning about a phenomenon profoundly, subject knowledge is the basis (Wolff et al. 2019). Finnish schools must offer the students at least one week of multi-disciplinary studies every year (Finnish National Board of Education 2014), and PhBL is an innovative way to teach about complex issues like climate change (Yli-Panula et al. 2020). Yet, the basis of such a multifaceted topic is deep subject knowledge, and it demands much more than one week of study.

PhBL has also been criticized for leaving the students without guidance. However, the teacher is responsible for the planning, implementation, and evaluation of the learning process (Lonka et al. 2015). Likewise, a PhBL approach requires a teacher willing to promote the students' cognitive, collaborative, and creative learning (Lonka 2018; Wolff and Ehrström 2020), and help the students deal with emotions (Lonka et al. 2015). Educational reforms and policy emphasizing alternative teaching strategies may gradually try to shift the responsibility from teachers to students. However,

[n]either teachers nor students alone contribute to successful learning outcomes, but within their responsive relation occurs a transformation that is the work of both. Approaches that neglect the responsivity of this relation risk turning teaching and learning into neoliberal practices in which the students not only receive all the blame if their endeavors fail but also, reflectively, ascribe this failure to themselves. (Symeonidis and Schwarz 2016, p. 42)

To meet the needs of the present time with complex crises affecting both humanity and nature, it is crucial to search for alternative, even unconventional, ways of teaching and learning that empower the learners and bring hope for the future. In the PhBL process, the students' own keen interest, responsibility, and activity are central (Lonka et al. 2015), but also ethical and existential elements. The teacher's role is to encourage genuine philosophical Bildung problems like who am I/are we, what am I/are we doing, why am I/are

we doing this, who do I/we want to be, and reflections on if the personal or joint chosen course is accurate (see Friesen 2017; Mollenhauer 2014; Wolff et al. 2019). Consequently, PhBL is one way, but not the only purposeful way to help the students to learn to see the world from both deep and wide critical perspectives, and to be willing to vision and plan alternative directions with many kinds of collaborators.

Phronesis

Nirmala Lee

Guildhall School of Business and Law,
London Metropolitan University, London, UK

Synonyms

Deliberation; Praxis; Prudence; Wisdom in action; Wisdom in practice

Definitions and Description

Phronesis is etymologically derived from the Greek φρόνησις, which means wisdom that has been acquired from learning and experience of

practical matters. Socrates is said to have equated phronesis with virtue in his dialogues (see Plato's *Meno*, circa 429–347 BC). Phronesis is known as an Aristotelian concept meaning “practical wisdom,” which is concerned with how to act wisely in particular situations. Aristotle considered phronesis to be an ethical virtue closely connected to the ultimate end of human well-being that is described as “eudaimonia” from both individual and societal perspectives. In *Nicomachean Ethics* (circa 240 BC), phronesis is distinguished from other terms for wisdom and intellectual virtues such as *episteme* and *techne* which translate as knowledge and art, respectively.

Phronesis introduces values into judgment and the decision-making process. The distinguishing quality of phronesis is the requirement to arrive at reasoned decision about action with regard to whether the outcome is thought to be advantageous (Martin 2015). Through “phronesis,” an “insider-researcher” can “make good practical judgements about their research practice” (Gibbs et al. 2007, p. 367). Phronesis is vital in relation to all matters that affect humanity including sustainability-related matters. While the Aristotelian concept of “*sophia*” means wisdom, the term implies theoretical wisdom which is not necessarily wisdom in practice. “*Praxis*” is closer in meaning to phronesis and refers to thoughtful doing and reflective practice, while phronesis refers to wisdom expressed in the domain of practice. Phronesis and *praxis* emphasize wisdom in action, not just wisdom in theory. The western Greek concept of phronesis has been equated with the eastern Buddhist concept of mindfulness (McEvilley 2002).

Phronesis and Ecological Wisdom

Two millennia after Aristotle, a jazz band formed in 2005 by Danish bass player Jasper Høiby took the name of “Phronesis.” The album cover to their 2018 release *We Are All* is a reference to the environmentalist John Muir. Muir was noted for being an ecological thinker and known as “John of the Mountains” and “Father of the National Parks,” being an early advocate for the preservation of wilderness in the USA.

Oliver and Dennison (2013) believe that the two terms phronesis and *praxis* describe what needs to happen in environmental science and that these two terms are at the core of developing a practical philosophy for environmental science: it is not adequate to have a knowledge of what needs to be done or recommend what should be done; action is also required, and this “doing” in terms of environmental science can take the form of protection or restoration activities. As a Professor of Marine Science and Vice President for Science Applications at the University of Maryland Center for Environmental Science (UMCES) in the USA, Dennison recognizes the importance of action in relation to environmental science and sustainability issues.

Competent project managers are required to take forward sustainability and environmental matters effectively, and phronesis and *praxis* are considered as key components of mapping standards and competence assessment approaches. The mediating role of *praxis* and *phrônêsis* between theory and practice is advocated by Bredillet et al. (2015) to resolve the tension between performance and attribute-based approaches to competence assessment.

The construct of *ecophronesis* (ecological phronesis) is posited by Xiang (2016) as the ecological practical wisdom that one might acquire in relation to the use of ecological practice; *ecophronesis* acknowledges the capabilities of ecological practice demonstrated by human beings or the *ecophronimos*, who, over thousands of years of human coevolution with nature, developed the master skill of ecological practical wisdom that enabled them to make, and act well upon, the right choices in challenging circumstances of ecological practice. Such ecological practical wisdom manifests itself in a myriad of ecological projects serving human beings’ enlightened self-interest and continues to evolve, as Xiang (2016) puts it, in a contemporary society of unprecedented socio-ecological transformations.

Summary/Conclusion

The concept of phronesis highlights the importance of practical wisdom and thoughtful action

in relation to all matters including those relating to sustainability and the environment. It is not adequate to know what needs to be done and even advocate what needs to be done. It is crucial that something is done and what is done is informed by practical wisdom. Phronesis is both an ethical virtue and an intellectual virtue (Eikeland 2008, p. 53) that must be acquired through practice rather than through the learning of theoretical knowledge. Phronesis enables its possessor to figure out “the right way to do the right thing in a particular circumstance, with a particular person, at a particular time” (Schwartz and Sharpe 2010, pp. 5–6).

Sustainability issues involve practical matters such as protecting the planet from environmental degradation and depletion of natural resources; preventing/reducing air, water, and soil pollution; and preserving the long-term health of ecosystems. Practical matters require practical reasoning. “Practical reasoning is deliberative, it takes into account local circumstances, it weighs trade-offs, it is riddled with uncertainties, it depends upon judgment, profits from wisdom, addresses particulars, it deals with contingencies, is iterative and shifts aims in process when necessary. Practical reasoning is the stuff of practical life. It is not the stuff of theoretical science. Its aim is to arrive at good but imperfect decisions with respect to particular circumstances” (Eisner 2002, p. 375). To sum up, what is needed is phronesis. As Dieppe (2011) has argued, it takes wisdom and experience, in addition to scientific data, to make the right decisions.

Definition

Currently, a common denominator of practically all nations, developed and underdeveloped, is the presence of a huge surface of soils and aquatic basins highly contaminated by the presence of elevated concentrations of multiple pollutants such as heavy metals, pesticides, dioxins, or surfactants. Because of this situation, it is necessary to consider nonaggressive, low-cost, and relatively efficient processes that can regenerate and purify polluted areas. It is at this point on which the Phytoremediation arose, namely a series of natural processes in which three natural sciences, botany, biology, and chemistry, cooperate toward the plausible restitution of soils and waters to their original state of healthfulness.

Introduction

Throughout the ages, techniques and procedures close to the modern Phytoremediation can be observed in the classical Greece or since the sixteenth century in the botanical works and biological treatises of A. Cesalpino, J. B. van Helmont, R. Hooke, M. Malpighi, or S. Hale (Landmeyer 2011). Many ancient civilizations realized that if nature was left to act freely, without restraint, the growth of certain plant species could contribute to the regeneration of contaminated sites, hence in the wars of conquest some cities such as Carthage were punished in perpetuity with the “punishment of salt” (Visonà 1988), that is, by pouring salt on the soil to ensure that the conquered area would no longer be able to regenerate and would never again be able to host human beings. The etymological roots of the term “Phytoremediation” derive from the combination of the Greek prefix “Phyto” – plant – and the Latin suffix “remedium” – healing – (Chakravarty et al. 2017; Cunningham et al. 1997), being a fairly modern word that was coined in the 1990s of the last century (Rai 2018) although it actually encompasses a series of practices that have been carried out since immemorial times. The modern origin of the term has contributed to the

fact that, in purity, it is an intuitive concept for which there is no unanimously accepted academic definition; in fact, Chakravarty et al. (2017) list up to five different definitions present throughout the scientific literature.

In general terms, Phytoremediation can be defined as a set of procedures in which plants and their associated microbes are utilized to depollute contaminated soils and water surfaces. The basic operating sequence can be observed in the Phytoextraction, one of the most widespread modalities or techniques of Phytoremediation, resulting in essence in a quite simple and ambitious mechanism given the enormous environmental degradation suffered by the planet: Plants act as environmental green livers, absorbing the different polluting elements that are found in the soil and water from their roots. Subsequently, these harmful elements are dispersed by the plant itself to its aerial parts which, after the whole process, can be combusted to obtain clean energy, while the metals can also be recycled from the subsequent treatment of their ashes (Chakravarty et al. 2017).

Characteristics of Phytoremediation

The gradual arrival of the Industrial Revolution to the four corners of the planet (Kumar et al. 2017) as well as mining, military, and agricultural activities led to the continuous impoverishment and intoxication of soil and water (Kumar et al. 2017), since an effective detoxification in the short-medium term would mean a substantial application of economic and technological resources that not all the world's economies can afford. Peuke and Rennenberg (2005) estimated that more than 16% of the European Union suffers from some type of soil pollution, hence it is calculated that only in this area there are between 300,000 and 1.5 million of contaminated sites, considering an economic impact of 59,000 to 109,000 million Euros. Phytoremediation solves these shortcomings at a relatively affordable cost for the public finances (Greipsson 2011) since it has proven to be a valuable alternative instrument. As Watanabe (1997, p. 1) stated: “Plants ranging

from pennycress to poplar trees are proving their worth as cleanup tools.” For these compelling reasons, European and North American environmental authorities have initiated significant programs aimed at promoting the public recognition of the advantages derived from Phytoremediation (E. P. A. 2012; Sharma 2018).

In comparative terms, Phytoremediation will be more effective in large areas with pollution levels that normally range from medium to low, in the same way that not all plants are equally suitable to be successful in this type of process by depending, essentially, on the following factors: the level of tolerance to a given pollutant component, the ability of plants to locate and isolate the pollutant elements in their aerial zones (“translocation”), as well as other aspects such as their resistance to insects, the type of soils, the pH levels, etc. (Chakravarty et al. 2017).

It is also fundamental that plants behave as “hyperaccumulators,” i.e., a peculiarity owned by certain kinds of plants to absorb metals from the soils and accumulate them above a threshold considered efficient (Fernández et al. 2010). In this discipline, the level of efficiency is given by three elementary coefficients (Chakravarty et al. 2017): Enrichment Coefficient (EC ratio or level of heavy metal concentration in those plants grown in contaminated sites), Translocation Factor (TF index, which determines the path of metals from the roots to the shoots of a given plant), and the tolerance index (TI, which determines the appropriateness of any plant for application in a Phytoremediation process). These measures are trivially calculated by using the respective formulas:

$$EC = \frac{\text{Metal concentration in roots or shoots}}{\text{Metal concentration at the site}},$$

$$TF = \frac{\text{Metal concentration in plant shoots}}{\text{Metal concentration in plant roots}},$$

$$TI = \frac{\text{Biomass of plants cultivated in contaminated soil}}{\text{Biomass of plants cultivated in control conditions}}.$$

According to Kvesitadze, Khatisashvili, Sadunishvili, and Ramsden (2006), the environmental contaminants combated by Phytoremediation cover the following spectrum of pollutants: benzenes, chlorinated alkanes and alkenes, dioxins, gaseous contaminants, pesticides, phthalates, polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), surfactants, and trinitrotoluene (TNT) in addition to, naturally, heavy metals. The latter are usually the main target of these procedures hence their wide profusion in the scientific literature (Kadukova and Kavuličova 2010; Nedjimi 2021; Shah et al. 2010; Tangahu et al. 2011; Yan et al. 2020), not to mention the transcendental advances in nuclear cleanup by removing radionuclides from contaminated soils due to hypothetical nuclear accidents (Willey 2007). Figure 1 summarizes the heavy metals whose effects are

usually counteracted by techniques based on Phytoremediation.

For their part, Surriya, Saleem, Waqar, and Kazi (2015) pointed out that more than 400 different plant species have sufficient potential to assist in the cleanup of polluted sites. In this regard, Table 1 lists more than 100 botanical specimens that have been used to remove the waste produced by five highly polluting industries.

Phytoremediation has been evolving in several differentiated techniques or branches coming from the same common core, taking advantage of plant versatility as well as their associated microbes. In Fig. 2, the main approaches linked to this discipline are outlined, taking into account that there are also other auxiliary procedures rather less widespread such as the Dendroremediation (Komives and Gullner 2006)

Phytoremediation, Fig. 1 Main heavy metals eradicated from the environment as a result of the Phytoremediation. (Source: Author's own elaboration)

or the Hydraulic control (Kadukova and Kavuličova 2010).

In line with Bose, Rai, Bhattacharya, Chaudhuri, and Bhattacharyya (2010), Chandra and Kumar (2017), Chakravarty et al. (2017), Kumar et al. (2017), Ssenku et al. (2017), and Tiwari, Kumar, and Kumar (2017), each of the procedures indicated in Fig. 2 is briefly outlined below. It should be noted that, in the same way that there is no univocal definition of the term Phytoremediation, neither is there a uniform definition of its associated techniques and procedures.

- **Phytoextraction.** It can be considered as the type-procedure of Phytoremediation, consisting in the absorption, translocation, and accumulation of pollutants in the aerial biomass of plants. In this way, it is possible to purify soils of pollutants, especially by eliminating metals of a toxic nature. This approach is the most widely implemented and the one that has resulted in the greatest economic benefits.
- **Phytofiltration.** It filters pollutants out of water environments from groundwater, soil humidity, or the water used for agricultural irrigation. It can be of two different types, one via the roots which is known as rhizofiltration and the other through seedlings which is commonly known as blastofiltration.
- **Phytostabilization.** It is also known as Phytorestitution and entails the immobilization and/or accumulation of toxic compounds in the soil or groundwater, or the stabilization of the soil itself to prevent erosion.
- **Phytovolatilization.** This method involves the release into the atmosphere of pollutants deposited in the soil through the plants' foliage. In short, the toxic compounds are taken up from the soil by the roots through the absorption of the water in which the pollutants are deposited, which are then released directly into the air through the transpiration, converted into volatile substances (in the form of gases).
- **Phytodegradation.** It refers to the application of plants and their attached microorganisms to decompose organic pollutants by the enzymatic degradation of harmful substances to less toxic elements by means of the root exudates and cell enzymes. It can occur either within the plant or within the rhizosphere of the plant.
- **Rhizodegradation.** The natural action of plants leads to the stimulation of rhizosphere

	Distilleries	<i>Achyranthes aspera</i> (chaff flower), <i>Amaranthus spinosus</i> (amarant), <i>Basella alba</i> (pui), <i>Blumea lacera</i> (janglimuli), <i>Cannabis sativa</i> (Bhang), <i>Chenopodium album</i> (goosefoots), <i>Croton bonplandianum</i> (Ban tulsi), <i>Dhatura stramonium</i> (dhatura), <i>Kalanchoe pinnata</i> (life plant), <i>Parthenium hysterophorous</i> (Congress grass), <i>Ricinus communis</i> (castor oil plant), <i>Sacchrum munja</i> (munja), <i>Setaria viridis</i> (green foxtail), <i>Solanum nigrum</i> (kali makoy), and <i>Trichosanthes dioica</i> (parval)
	Pulp and paper mill	<i>Alternanthera sessilis</i> , <i>Amaranthus cruentus</i> , <i>Amaranthus spinosus</i> , <i>Cannabis sativa</i> , <i>Centella asiatica</i> , <i>Chenopodium album</i> , <i>Colocasia esculenta</i> , <i>Commelina benghalensis</i> , <i>Cyanthillium cinereum</i> , <i>Cynodon dactylon</i> , <i>Diplazium esculentum</i> , <i>Eclipta prostrate</i> , <i>Eichhornia crassipes</i> , <i>Eleusine indica</i> , <i>Eragrostis atrovirens</i> , <i>Fimbristylis bisumbellata</i> , <i>Fimbristylis dichotoma</i> , <i>Hydrilla verticillata</i> , <i>Ipomoea aquatic</i> , <i>Jussiaea repens</i> , <i>Lemna minor</i> , <i>Leucas lavandulifolia</i> , <i>Ludwigia hyssopifolia</i> , <i>Mikania micrantha</i> , <i>Nicotiana plumbaginifolia</i> , <i>Parthenium hysterophorus</i> , <i>Phaseolus vulgaris</i> , <i>Phragmites communis</i> , <i>Pista stratiotes</i> , <i>Ricinus communis</i> , <i>Solanum americanum</i> , <i>Sonchus arvensis</i> , <i>Trapa natans</i> , and <i>Triticum aestivum</i>
	Tannery	<i>Abelmoschus esculentus</i> (Okra), <i>Allium sativum</i> (Garlic), <i>Amaranthus blitum</i> (Amaranth), <i>Artocarpus heterophyllus</i> (Jack tree), <i>Brassica campestris</i> (Yellow mustard), <i>Brassica juncea</i> , <i>Brassica nigra</i> (Black mustard), <i>Brassica oleracia</i> (Cauliflower), <i>Calotropis procera</i> (Calotropis procera), <i>Cannabis sativa</i> (Hemp), <i>Capsicum annuum</i> (Chilis), <i>Cassia fistula</i> , <i>Chenopodium album</i> (Pig weed), <i>Coriandrum sativum</i> (Coriander), <i>Cucumis sativus</i> (Cucumber), <i>Curcuma domestica</i> (Turmeric), <i>Lagernaria siceraria</i> Molina Standley (Bottle gourd), <i>Luffa aegyptiaca</i> Mill. (Vegetable sponge), <i>Momordica charantia</i> (Bitter gourd), <i>Phaseolus vulgaris</i> (Kidney bean), <i>Ricinus communis</i> (Ricinus communis), <i>Saccharum officinarum</i> (Sugarcane), <i>Sida acuta</i> , <i>Solanum melongena</i> (Eggplant), <i>Solanum tuberosum</i> (Potato), <i>Sorghum tuberosum</i> (Sudan grass), <i>Spinacia oleracia</i> (Spinach), <i>Trigonella foenum-graecum</i> (Fenugreek), <i>Triticum aestivum</i> (Wheat), and <i>Zea mays</i> (Maize)
	Textile	<i>Alternanthera philoxeroides</i> , <i>Aster amellus</i> , <i>Blumea malcolmii</i> , <i>Brassica juncea</i> , <i>Glandularia pulchella</i> , <i>Hydrilla verticillata</i> , <i>Ipomoea hederifolia</i> , <i>Nasturtium officinale</i> , <i>Petunia grandiflora</i> , <i>Phragmites australis</i> , <i>Portulaca grandiflora</i> , <i>Rheum rhabarbarum</i> , <i>Rosmarinus officinalis</i> , <i>Tagetes patula</i> , <i>Thymus vulgaris</i> , <i>Typha angustifolia</i> , <i>Typha domingensis</i> , <i>Typhonium flagelliforme</i> , and <i>Zinnia angustifolia</i>
	Petroleum	Alfalfa (<i>Brassica campestris</i>), Alfalfa (<i>Medicago sativa</i>), Bermuda grass (<i>Cynodon dactylon</i>), Broad bean (<i>Vicia faba</i>), Crabgrass (<i>Digitaria sanguinalis</i>), Ryegrass (<i>Lolium perenne</i>), Smooth meadowgrass (poapretensis), Switchgrass (<i>Panicum virgatum</i>), Tall fescue (<i>Festuca arundinacea</i>), and Water hyacinths (<i>Eichhornia crassipes</i>)

microorganisms to induce the enzymatic decomposition of pollutants.

- **Phytodesalination.** It consists in the use of halophilic plants to reduce the alkalinity of saline soils in order to facilitate the common growth of any other type of plant. Halophilic plants, coming from saline environments (e.g., salt marshes or marine dunes), are generally employed as they are also better adapted to counteract the heavy metals than glycophytic plants. The latter represent the majority of cultivable plants and are characterized by retaining the sodium in the root as a

self-defense mechanism, so they cannot tolerate environments with an extremely high salinity.

Summary

The contributions of Phytoremediation to environmental sustainability are undeniable. According to Chakravarty et al. (2017), its achievements are manifold: the elimination of pollutants, the creation of employment, the social development, the “carbon sequestration,” or the generation and saving of alternative energies.

Phytoremediation,

Fig. 2 Overview of the key techniques on which the Phytoremediation is grounded. (Source: Author's own elaboration based on Chakravarty, Bauddh, and Kumera (2017))

Nevertheless, it also has a series of obvious limitations as it is a nonimmediate process which depends on the climate, age, and plant type, as well as on several edaphic factors (Chakravarty et al. 2017). Precisely, this last constraint justifies the research on genetically modified plants focused directly on its application in techniques related to Phytoremediation (Macek et al. 2006) which make them resilient to the soil pH, alkalinity, dryness, or the threat of plagues in the same way that the transgenization has to enhance their qualities as hyperaccumulators of heavy metals (Jha et al. 2017).

Basically, the main lines of research in this wide field have been directed to expand the functions of aquatic plants in environmental regeneration (Dhir 2013), to analyze Phytoremediation as an essential element in the production of Green Energy (Jha et al. 2017; Kumar et al. 2017; Surriya et al. 2014; Tiwari et al. 2017) or to channel the existing links between Phytoremediation and Biofortification, since both disciplines can

cooperate in unison in the environmental remediation and in the supply of micronutrients for human beings (Yin et al. 2012). Although Phytoremediation is not a Panacea, it opens a gateway to environmental regeneration, in an effective way and at costs that can be assumed by the community while creating a dense synergistic network that generates important economic and social benefits. However, it is not yet globally regulated, and it seems rather unlikely that these techniques will be accepted by all sectors of the society (Cunningham and Berti 2020), probably because of the scarce information that still exists about these procedures.

Pigou's Tax

Definition

Compensatory (corrective) tax. The Pigouvian taxation aims to optimize the use of resources by creating conditions for economic choice and counteracting market failure. This is a tax that is levied on each unit of pollution created by an organization—pollutant equal to the marginal pollution damage at an effective production volume. This tax is levied on the creator of “negative externalities.” The tax is intended to include the public cost in the private cost of the polluter. Its monetary value must be equal to the amount necessary to increase the private cost of polluters to the marginal social costs.

Introduction

Pigouvian Taxation or “Pigou's Tax” is a concept that bears the name of the creator of the idea of introducing offsetting fees, the English economist Arthur Cecil Pigou (1877–1959) an affiliate to the Cambridge School of Economics, neoclassical economist, president of the Royal Economic Society, founder of the microeconomic market failure school (Leeson 2014, p. xi).

Pigou presents the philosophy of the “compensatory tax” in his work “*The Economics of Welfare*”, first exposed in the following text: “Corresponding to the above investments in which marginal trade net product falls short of marginal social net product, there are a number of others in which, owing to the technical difficulty

of enforcing compensation for incidental disservices, marginal trade net product is greater than marginal social net product. Thus, incidental uncharged disservices are rendered to third parties when the game-preserving activities of one occupier involve the overrunning of a neighbouring occupier's land by rabbits—unless, indeed, the two occupiers stand in the relation of landlord and tenant, so that compensation is given in an adjustment of the rent. They are rendered, again, when the owner of a site in a residential quarter of a city builds a factory there and so destroys a great part of the amenities of the neighbouring sites; or, in a less degree, when he uses his site in such a way as to spoil the lighting of the houses opposite: or when he invests resources in erecting buildings in a crowded centre, which, by contracting the air space and the playing-room of the neighbourhood, tend to injure the health and efficiency of the families living there. Yet again, third parties—this time the public in general—suffer incidental uncharged disservices from resources invested in the running of motor cars that wear out the surface of the roads. The case is similar—the conditions of public taste being assumed—with resources devoted to the production and sale of intoxicants. [. . .] (Pigou 1920, pp. 161–162).

Development of the Concept

Pigou's tax is imposed on producers of negative external effects called "*negative externalities*." For the first time, Karl William Kapp explored the externalities (Kapp 1950, p. 14). Negative externalities are not included in the manufacturer's costs. In this way, the price of the goods on the market is inconsistent with their full cost and the manufacturer's commercial profits are unrealistic. These costs are not included in the cost of the producer. The producer transfers them onto society. The community is burdened with these private costs while the one who creates them receives non-market-based unwarranted profit. This situation is called "market failure" as

the producer of negative externalities transfers part of its costs onto society but only assigns revenue and receives price advantages over its competitors.

External effects influence the efficient allocation of resources through the market price mechanism (Baumol 1972, pp. 307–322).

In a situation of "market failure" where the market mechanism does not automatically and fairly take into account the price of the goods, a "third person" must intervene to correct the "failure." This third person is the state. Therefore, the Pigouvian Tax is also called a "corrective tax," a tax that corrects "market failures" or "market imperfection" (Lee 1975, p. 70). The correction of a market failure is to compensate society for damages and costs it has incurred due to the business of companies. These companies are in debt to society as it has covered the damages and costs of the companies' activities and the companies have appropriated profits without having made the full costs of acquiring these profits (Fig. 1).

Private creators of negative external costs transfer their costs to the public or third parties and monetize revenue. This distorts the effect of mechanism and competition.

By imposing Pigouvian Tax, the marginal costs of private producers of goods and services are raised to the level of the maximum public allowance (Lee 1975, p. 70). This is called "internalization of the externalities."

Pigou is the first economist to raise the issue of economic analysis of environmental protection, which is part of the concept of sustainable development today.

He also describes the instability of an economy as "*. . . this 'natural' tendency of people to devote too much of their resources to present service and too little to future service. . .*" (Kula 2006, p. 84).

Pigou's tax is used as a tool to reduce the pollution from a company's activities. Pigou examines the impact of taxes on pollution in production. According to Pigou, this pollution tax is an incentive for the polluter to reduce pollution and thereby reduce its negative impact on the environment. It is accepted, as Pigou accepts, that the strife of companies to pay less tax will

Pigouvian Taxation, Fig. 1 Graphic representation of the Pigouvian Tax. *MSP* Marginal Private Cost, *MSC* $MPC + \text{externalities}$, *MSB* Marginal Social Benefit ~

demand of good, *MSB* $MSC + \text{Pigouvian tax}$ -internalization of externalities

force them to change the technology that is polluting the environment with an ecological one.

Negative external effects can also be created by consumption. For example, when green areas, children’s playgrounds, and cultural monuments are taken away from the community for the construction of private buildings.

External negative effects can be grouped in the following direction: production–production; production–consumption; consumption–production; consumption–consumption.

The application of the Pigouvian tax on reducing environmental impacts is a contemporary method of reducing the harmful impact on the environment and that of private interests on the deterioration of the quality of life of society as a whole. Pigou’s tax is used to regulate negative environmental effects, along with other tools such as cap-and-trade and carbon allowance. It is a means of “internalizing negative externalities.”

Pigouvian taxes should not be confused with taxes on production. Pigouvian taxes are taxes on pollution. Pigouvian taxes are not environmental charges (Perelet et al. 2014, p. 158). The logic of the Pigouvian corrections is also the granting of subsidies to market agents that have reduced pollution.

Internalization of Negative Externalities by Levied Pigouvian Tax

W. Kapp was the first scientist to seriously explore the outsiders and believes that if their price is determined, they can be “internalized.”

Example of internalization of negative externalities of the “production-type” type:

Let’s take two companies: A—a coal-fired power plant (TPP) emitting harmful gases into the atmosphere, and B—a bio-vegetable

production plant. Company A creates negative outlets for company B.

Business expenses can be described with Cost A (A, x) and Cost B (B, x).

The government introduces a Pigouvian Tax for each ton of pollution generated by Company A. The condition that each unit of pollution reduction of the TPP in company A should lead to an increase of a unit of bio-vegetable production at company B, to balance the system, should be taken into account.

The task of the polluter company A when imposing the Pigouvian tax is as follows: the maximum production capacity minus production costs minus Pigouvian tax on production:

$$\max_{a,x} PAA - CA(A, x) - tx$$

The meaning of the Pigouvian tax concerning negative externalities is to internalize environmental pollution, that is, to include the price of the polluting company's output the non-included costs for its production that it has transferred to the public (Full Cost). Internalization can be described as follows (Fig. 2):

$$FCA = FP + \sum En \tag{1}$$

Where:

- F_A —full cost of production
- E —negative externalities
- Σn —Pigouvian tax

The analysis shows that the amount of the Pigouvian tax, which internalizes the outsiders, leads to a reduction of the production that pollutes thus reducing the pollution. If a company wants to remain on the market, it must reduce negative externalities (pollution to increase production).

Conclusions

The Pigouvian tax is imposed on entities and individuals that create negative externalities by their activities. An external effect is an impact that is not mediated by the market. The Pigouvian tax is currently applied to discharges of pollutants

P

into the environment, excise duties on harmful goods, entry fees to the city center or to the territory of natural and cultural parks, etc. In practice, in our days these are taxes on environmental pollutants such as petroleum products, dangerous substances, cigarettes, and the like. The Pigouvian tax can also be used to redistribute resources for the benefit of society.

Planned Obsolescence

Gizem Aras Beger

Faculty of Business, Department of Business Administration, Yasar University, Izmir, Turkey

Built-in obsolescence; Intended obsolescence; Product obsolescence; Programmed obsolescence

Definition

Planned obsolescence (PO) is the deliberate shortening of the usable lifespan of a product to accelerate the pace of consumption. It can be defined from either the company's or consumer's perspective. From the former perspective, PO can be considered as part of the product replacement strategy whereas it is part of marketing strategy from the latter perspective.

As an economic strategy, PO originated in 1932 during the Great Depression in the USA. Bernard London suggested it as a means to end the recession by stimulating turnover, reviving the consumption cycle and boosting the economy. Through various PO mechanisms, companies would motivate consumers to repeat purchases more quickly.

These mechanisms are scattered across many product-related factors based on purposefully reducing a product's lifespan. There are three types of obsolescence: *obsolescence of desirability*, *obsolescence of quality*, and *obsolescence of function*. Each emphasizes different ways to encourage repetitive purchasing by manipulating product features like durability, reparability, and design.

Today's so-called "throwaway society" culture vividly reflects this fast consumerism and

production pattern. However, the excessive post-consumption waste caused by PO presents a major challenge for sustainability. Yet no matter how heavily PO is criticized as a negative business strategy, some argue that it has some benefits. Gaining a sustainable point of view and then creating a strong sustainability culture requires deeper understanding across all layers of society as well as creating new paths for doing business.

Planned Obsolescence: An Explanation and Brief History

The concept of PO originated with the competition between General Motors and Ford in the early 1900s' automotive industry (Keeble, 2013). Another early sign of this trend was the Phoebus cartel, formed in 1924 by light bulb manufacturers like Phillips, Osram and General Electric, to artificially reduce bulbs' lifetimes (Hadhazy, 2016).

The strategy of limiting the normal usable life of products is called PO (Rivera & Lallmahomed, 2016). The term PO was first officially used in 1932 by Bernard London from the University of Wisconsin – London in a brochure entitled “*Ending the Depression through Planned Obsolescence*” (Satyro et al., 2018). It was offered to government as a planning strategy to end the recession (Çetiner & Gündoğan, 2014) and as a means of creating consumption need through shortening product lifecycles (Rivera & Lallmahomed, 2016). The idea was then popularized by journalist and social critic Vance Packard in “*The Waste Makers*” (Packard, 1960). He criticized PO and its broader consequences for society (Park, 2016; Cooper, 2017).

Types of Planned Obsolescence

PO exists in multiple forms at all stages of the product life cycle (Longmuss & Poppe, 2017). According to some, this versatility is expressed through different strategies, including advertising and product design, to offer multiple paths to reaching goals (Wieser, 2016). It is particularly common in several business sectors, like fashion

and technology, that provide a diverse range of products, such as accessories, furniture, personal hygiene goods, laptops, mobile phones, apparel, and cars (Rivera & Lallmahomed, 2016; Wieser, 2016).

There are different types of PO mentioned in the literature used with different names. However, the main ones are *obsolescence of desirability*, *obsolescence of quality* and *obsolescence of function*, which in turn has two subtypes: *systemic obsolescence* and *postponed obsolescence* (Longmuss & Poppe, 2017).

The first type, which is also known as *psychological or style/stylistic obsolescence*, is mainly based on consumers' psychological states rather than products themselves (Maitre-Ekern & Dalhammar, 2016). This type of obsolescence is actually about the subjective aging of a product in terms of its appearance or design as a result of changing consumption patterns or technological and fashion trends (Proske et al., 2016). Consumers and product designers are seen as key drivers of such obsolescence (Proske et al., 2016; Spinney et al., 2012). The clothing industry in particular proceeds by appealing to this basic human desire (Whiteley, 1987), which can cause addiction to newness, or “neophilia” (Hellmann & Luedicke, 2018).

Obsolescence of quality, also known as *technical obsolescence*, is more concerned with products that are designed to wear out after a given period (Sheehan, 2014; Rivera & Lallmahomed, 2016). That is the durability of the product and its components are artificially reduced (e.g., disposable cameras) (Longmuss & Poppe, 2017).

Obsolescence of function refers to situations where a product becomes old-fashioned in the eyes of consumers when technological advances enable technically superior products to be manufactured (Rivera & Lallmahomed, 2016; Cooper, 2017), such as with smartphones or computers. For instance, Apple's iPhone 5, released in 2012, sold with a new immovable adapter alongside other novel features (e.g., a unique Apple chip), which led to extra purchases (Maitre-Ekern & Dalhammar, 2016). Finally, within this category, systemic obsolescence involves modifying the current product's system to make it more

difficult to use (e.g., software updates and upgrades) (Amankwah-Amoah, 2017), while postponed obsolescence involves introducing a new product into the market despite even through the current product's technology is still performing better (e.g., Sony PS2 games console) (Cresswell, 2002).

The Impact and Criticisms of Planned Obsolescence

While PO is still a popular business strategy (The Washington Post 2012), it also continues to be harshly criticized for its negative social and environmental consequences (Pangburn & Stavoulaki, 2014). These criticisms began around the time of Packard's (1960) relatively well-known critique. According to Packard, PO is strictly based on consumer exploitation and wasting resources (Aladeojebi, 2013). Conversely, critics like Philip Kotler, a marketing guru, claim that PO is a driving force for technological advances or improvements, and a method of doing business for free societies in competitive industries (The Economist, 2009). Others argue that it provides employment and improves products and services (Aladeojebi, 2013). Defenders of PO also claim that new products are more eco-friendly, such as using less water or energy, than old ones (Satyro et al., 2018).

Regardless of the criticisms, PO certainly has massive drawbacks for both society and environment (Michel, 2017). Today's competitive business conditions push consumers and producers to use more materials and energy, which causes overproduction and overconsumption of non-durable items (Michel, 2017).

Even as many more are produced, huge amounts of goods like cell phones and personal computers are discarded each year (Guiltinan, 2009). This results in tremendous damage through increased waste, resource consumption, depletion of scarce natural resources, greenhouse gas emissions and other pollution (including chemical leakages from unrecycled waste) (Wieser, 2016). Nevertheless, society seems to have been conditioned to desire and demand this kind of change, despite the high risk of corrupting society.

Unfortunately, therefore, PO is an unsustainable practice in terms of production, consumption and waste generation.

Sustainable Approaches to Planned Obsolescence

Given the criticisms of PO, it is clear that progress away from a throwaway culture is needed across all layers of society, not just consumers or producers. Although some PO practices are still omnipresent in today's business world, some awareness of problems deriving from unsustainable practices has grown, especially recently (Satyro et al., 2018).

For instance, various efforts are being made by the European Union (EU) and its member states for a more sustainable future through legal mechanisms (e.g., European Economic and Social Committee and European Consumers Confederation). Moreover, EU rules, such as the Unfair Commercial Practices Directive or EU labeling rules, incentivize producers and consumers toward more durable and sustainable products (Michel, 2017). Similarly, the World Business Council on Sustainable Development encourages consumers to choose more sustainable products and services (Guiltinan, 2009).

However, it should also be acknowledged that high levels of competition, complexity, costs and increasing speed of production, consumption and innovation cycles leave virtually no space to companies for sustainable development (Longmuss & Poppe, 2017). Consumers are also seen as key actors, with the power to reverse this fast consumption trend (Cooper, 2017) through their interests, expectations, and demands for sustainability (Longmuss & Poppe, 2017). They can thus pave the way for improving goods and services, or even new business models for producers and commerce. A few studies already take a positive approach to PO by suggesting how it can be used within the frame of the circular economy (e.g., Van der Laan & Aurisicchio, 2017; Longmuss & Poppe, 2017). This is believed to be particularly useful when used in hybrid combinations of intercompatible business models.

Summary

Given its contradictory qualities, PO is a controversial debate topic. However, the idea that PO has some benefits seems quite dangerous unless it is carefully incorporated within today's contemporary business world. The implementation of PO requires deeper understanding relating to sustainable production and consumption. Although there is already greater understanding in society, more meaningful and greener choices and comprehensive information are needed about these choices. In conclusion, all actors alone have limited choices for making such changes, so a holistic approach is needed to achieve sustainable development (Longmuss & Poppe, 2017).

Introduction

The wishes of building a more just, supportive, and fully sustainable world economy are inconceivable without first achieving the effective integration of women in all sectors and levels of the labor market. In fact, the systematic reduction of gender differences is one of the objectives set by the Rio de Janeiro Conference, so that in Agenda 21 (UN) the disparity between the sexes is expressly denounced: “(. . .) women are a particularly disadvantaged group.” These gender differences have not yet been completely eradicated; on the contrary, in some cases, they have been accentuated by the difficult access of women to education in various areas of the world (Barroso et al. 2017) among many other obstacles to be taken into account, such as sexist stereotypes, the psychological differences between women and men, or social roles atavistically associated with women like housework, childcare, etc. (Bertrand 2017). All of these impediments form an insurmountable and invisible wall that leads to significant gender differences, usually summarized by an iconic phrase coined by M. Loden during a panel discussion about women’s aspirations: “The Glass Ceiling” (BBC 2017). Of course, the differences between men and women are part of the United Nations Sustainable Development Goals 2030 Agenda (Bidegain Ponte and Rodríguez Enríquez 2016), so what is the point of betting on a fully sustainable world if women, one of its protagonists, continue to be discriminated in the twenty-first century?

Regardless of the fact that this discrimination is *per se* fallacious, illogical, and unfair, it is also seriously detrimental to the normal functioning of the companies where women carry out their work activities since, according to McNerney-Lacombe et al. (2008), the female collective, when compared to the male counterpart, provides greater efficiency in teamwork, resistance, resilience, and credibility (among many other aspects). Despite the fact that in existing literature there is an abundance of lines of investigation concerning the integration of women in the labor-business environments, very few have taken into account

two primordial elements: what do women think of themselves, in other words, how they conceive about themselves and, above all, if they feel “happy.” In this sense, at the end of the 1980s, two Canadian professors, D. C. Poff and A. C. Michalos (see 1998), designed a statistical methodology specifically aimed at measuring both considerations. Although this methodology was framed within *Feminism*, its applicability can be taken to any other sphere in order to determine the degree of satisfaction, i.e., happiness, of women within the human collective in which they are integrated, for example, in relation to the tasks that they commonly carry out in their employment. In this sense, this entry synthesizes the bases of the Poff-Michalos Feminism scale, reoriented toward the analysis of the level of happiness and satisfaction of women at work. The use of the Poff-Michalos procedure as a tool to evaluate the sustainability is based on a simple premise: the most adequate interlocutor to define the woman is herself and, obviously, an optimal development at work must always be linked to the fact of “feeling happy.”

The Parameterization of Women Versus Quality of Life

The conceptualization of the Poff-Michalos Procedure has its origins in a great number of works that focused on Women’s liberation movements around the world during the 1960s and 1970s. In the case of Europe, the French movement “May 68” had a special repercussion, contributing to the fact that women in this continent began to break the ties that, atavistically, discriminated against men. For its part, Canada was one of the countries in which the Women’s liberation movements made their presence felt most strongly, to such an extent that Poff (1985) set out how to carry out an epistemologization of this social positioning. Inevitably, as it became more prominent, Women’s liberation began to be measured in quantitative terms. For example, Alspach (1982) used an *ad hoc* three-item index of “non-traditional sex-role attitudes” while Beere et al.

(1984) elaborated an explicit measure to evaluate the attitude toward the perception of the degree of equality between sexes. On this theoretical-conceptual framework, the Poff-Michalos Procedure presents a series of evident improvements: it expressly introduces the component “quality of life,” relates it to “happiness” and, the one that prevails above all is the consideration that women have of themselves.

Descriptive Synthesis of the Bases and Applicability of the Poff-Michalos Procedure

The Poff-Michalos Procedure, as outlined in Fig. 1, is based on five levels of acceptability. Since it is a statistical procedure, it must be considered as an objective measure, free of interpretative bias as long as the population sample analyzed had been conveniently designed. The original implementation of this procedure used a sample of 413 undergraduate women at the University of Guelph, Canada, linking the *Feminism* phenomenon with several features of the quality of life as “happiness” and with the fact of “being a good person.”

Specifically, the application of the Poff-Michalos Procedure to measure the happiness/satisfaction of the female component in the work, as well as in the original formulation (Poff and Michalos 1998), starts from a series of basic hypotheses, outlined in Table 1, in addition to the structuring of the target sample to be analyzed according to three key parameters as indicated in Table 2: personal status (marital, employment, and country), age, level of education, and nearest family income. Note that, in any case, the segmentation of the target population has to be readjusted to the particular conditions of each company or country; hence the Poff-Michalos Procedure is not closed, but open to the evolution of the most important social variables, more particularly those that may be closer to the concepts “quality of life” or “happiness.”

Since the constructed scale is built on the basis of obtaining diverse subsets of representative

Poff-Michalos Procedure, The,

Poff-Michalos Procedure, The, Table 1 Baseline hypothesis of the Poff-Michalos Procedure. (Source: Own elaboration from Poff and Michalos 1998)

<i>H1.</i> Being a female worker as measured on the PMF scale is (statistically significantly) positively correlated with:	I. Considering oneself to be a feminist
	II. Describing oneself as happy
	III. Describing oneself as independent
	IV. Describing oneself as truthful
	V. Describing oneself as compassionate
	VI. Describing oneself as friendly
	VII. Considering one’s family and career as equally important
	VIII. Having high self-esteem
<i>H2.</i> Being a female worker is negatively correlated with describing oneself as competitive	
<i>H3.</i> Being a female worker is not correlated with describing oneself as being yielding, gullible, childlike, conventional, aggressive, conscientious, assertive, loyal, understanding, warm, willing to take a stand, individualistic, having leadership abilities, or loving children.	

items that are conceptually interrelated, those higher values of the Cronbach’s α (see Cronbach 1951) are employed in order to definitively configure the measure of happiness-quality of life for the female personnel of each company, which allows to know at first hand which are the feelings and motivations of the feminine collective in a given company, as well as whether the policies of feminine integration are being carried out

adequately, in order to fulfill the established sustainability objectives.

Conclusions

Much has been said about the existence of a “glass ceiling” among working women, that is, a metaphor usually adopted to identify how the

			Total	<i>N</i>	100%

difficulties that the female collective encounters at the highest business levels are much greater than at the lower echelons (Cotter et al. 2001), which may also be related to a certain invisible barrier that represents the fear of failure or, simply, that women may feel self-conscious representing a clear minority compared to men. This gap, which is not completely overcome at present (Valls Martínez et al. 2021a), continues to be not only a sustainable objective but also one of the great challenges of contemporary Corporate Social Responsibility (Valls Martínez et al. 2021b).

However, despite the predominance of quantitative investigations focused on justifying the gender difference based on socioeconomic variables, it is rarely justified in the light of whether women, within a context of supposed equality with men, are fully happy and enjoy a relative quality of life. The

analysis of this reflection is even more important if it is conducted by the women themselves, which is why this entry has promoted the use of the Poff-Michalos Procedure (Poff and Michalos 1998), not only from an exclusively *Feminist* perspective but because it represents an objective measure of the performance of women in their workplaces when it comes to considering themselves happy.

Definition/Description

Policy and Military Force Sustainability is committed on a model that develop financial, social, and economic perspectives which undertake actions on the society to answer to crisis, to prevent conflicts, and to build each day peace to the citizen.

Introduction

All over the world, security is recognized as fundamental to live in a society (EU 2014b). Inevitable threats, such as international terrorism, proliferation of weapons of mass destruction, resource and energy shortage and blackmail, regional and local conflicts, national domestic destabilizations and collapse of states, growth of organized crime, and rise in xenophobia and social unrest over national, religious, and cultural differences (Everts 2004) demand cause analysis that bring to the public knowledge the most effective responses (WWF 2017). Indeed, ignoring political, ethnic, religious, social, and economic sources of conflicts, that some Governments already do, it is not dedicated to a world in which humanity and nature are promoted in total harmony (WWF 2017).

This tendency has been strengthened by the European Union publication about the Global Strategy for the European Union's Foreign and Security Policy (EU 2016). This strategy aims to

promote peace and guarantee the security of the citizen and their territory as shared interest and principles. More than a vision, it proposes prosperity of the citizen, resilience of democracy, rules-based global order that bring the positive change and answer to the society through actions of the policy and military force sustainability (Juncos 2017).

According to European Parliament (EP 2019), each Member State of the European Union agrees on the need to promote, to develop, and to maintain a competent and competitive European defense based on their capabilities. In order to achieve this objective, each Member State use several instruments, as far as, the Community Law is concerned, aiming to achieve a truly European defense and equal competition on European global markets. Also, the Member States contribute to the in-depth development of the diversity of the European base of defense-related suppliers, in particular, by supporting the participation of small- and medium-sized enterprises and nontraditional suppliers in the European defense industrial and technological base, as well as fostering industrial cooperation and promoting efficient and apt lower level suppliers.

The emphasis on the rapid and extensive transformations due to the Government Policies (i.e., International Monetary Fund with Debt crises in Greece) and Other Institutions' decisions (i.e., International Labour Organization indicates that 168 million children aged 5–17 are engaged in child labor (UNICEF 2014)) has greatest impact on the world due to the application of different types of policies (Kassow 2018).

Other example is the environmental policy with waste management (i.e., nuclear waste with Spain and Portugal Border (Agência Reuters 2017)), as well as the social security policy with social benefits (i.e., types of pensions and retirement income in France with Yellow vest movement (Viscusi 2019)). Certainly, Han and Demircioglu (2018) states that the sustainability policies associated with the Government of a Member State of European Union or other country all over the world are specially inserted on the debate of the conflict between individuals and groups of the society that achieve or wish to achieve the power and control of the same of these new tendencies.

Truly, as Bailes (2009) argues, the EU's deepest interest lies in making others – and eventually the world – more like itself. Hence, the accountability is important for the democratic control imposed on public administration systems. For example, in Portugal and according to AR (2013a), the restoration of the financial stability and the economic growth are sustainable with respect to the employment generation system and it is indispensable for strengthening national security. Consequently, the support for this sustainable development demands new challenges of the policy and military forces which has been assigned to missions of public interest and constitutionally mandatory in order to increase of the quality of life of the citizen.

Undeniably, the crisis of politics' impacts on the sustainability of the policy and military force led to social protests not only against social and economic policies but also against the integrity and the responsibility of the political elite. This integrity is a serious problem in many countries (Benito 2018), due to corruption that diminish truth, honest dealing, and skepticism (Moses 2011). Alongside, the responsibility encompasses protection depending on their scale against hazards in all economic activity through four principles: social contract, transparency, accountability, and sustainability (Crowther and Rayman-Bacchus 2004).

Sustainability is much more than a model of development created for the future generations and addresses decisively the citizenship throughout their country. So, this model cannot be realized without peace and security and self-determination of Policies and Military forces removing obstacles which adversely affect the expenditure ratios based on the best international practices. So, sustainable impacts on violence, insecurity, and injustice within the framework of social, environmental, and economic perspectives are aimed to improve the effectiveness and the efficiency in vulnerable situations.

The need of financial sustainability of the national defense strategy is viewed with continuous improvement bringing together governments, the private sector, civil society, and the European Union. Thus, the Article 2 of the Regulation (EU) n° 233/2014 of the European Parliament and of the Council establishes the financing instrument

for development cooperation for the period 2014–2020 (EU 2014a) defining objectives of the Union’s external action and of the European Consensus and agreed modifications therefore with the primary objective of cooperation under this Regulation shall be the reduction and, in the long term, the eradication of poverty and consistently with the primary objective referred to cooperation under this Regulation shall contribute to fostering sustainable economic, social, environmental development and consolidating and supporting democracy, the rule of law, good governance, human rights, and the relevant principles of international law.

In this context, the concept of Policy and Military Force Sustainability is based on the model which provides their stakeholders to prevent and to manage crisis and ensures the reduction of threats that affect the active promotion of peace, stability, human rights, democracy, in general, and the security of the citizen of one country or State, in particular (EP 2019).

In the security and military policy and strategy acts with blindness will cause more threats to their sustainability. In recent decades, Policy and Military Force Sustainability must fight, for example, uncertainty and unpredictability of the European Union’s borders, and this may cause immediate neighborhood problems (i.e., North Africa, Middle East, Caucasus, Balkans, Eastern Mediterranean, Russian, Ukraine, and Georgia) as well as the extended neighborhood problems to other parts of the world (i.e., Sahel and Horn of Africa). Controversy at internal- and external-level security of each Member State of the European Union is known for Policy and Military Forces (EP 2019), but these require fighting abuses of power in all institutions and by each citizen.

The public policy analysis has undergoing major changes and theory developments that affect practitioners (Sabatier 2006). According to Baldwin (1997), several policies made by Governments take proposals to prioritize threats, such as human rights, economic crises, environment damage, drug trafficking, epidemics, crime or social injustice, as well as the traditional concern for the security of external military fights.

On the one hand, the strategic policies of the policy and military forces must be made on the

sustainable model in which they are applied in existing areas of conflict. According to AR (2013a, b), it is important to identify the lines of action to ensure the macroeconomic stability and the financial balances of the economy, guaranteeing the sustainability of the public accounts and the implementation of measures that reflect the indispensable connection between environment, food, public health, and land use, in order to increase the security of the territory, communities, and citizen, both from a perspective of prevention and adaptive risk management and from a proactive perspective with prospect of strengthening resilience.

On the other hand, it is important to define the effort for the acquisition and for maintenance of strategic reserves of medicines that can be used in case of emergency or in public health disaster, as well as to ensure, in a sustainable manner, the preservation of essential infrastructures, integrating the care system and both in the field of supply of essential goods such as water, food, and energy (WWF 2017).

These environmental issues have become unavoidable, taking prominent positions on all political agendas of States and Other Organizations (Kettunen et al. 2018). The principles of sustainability in the policy and military forces are the current awareness that survival depends on the conservation and rational use of resources. Thus, the Ministry of Defence will solve conflicts in the society through the expansion of the preservation of biodiversity and natural ecosystems, and it will encourage to reduce harmful conflict of interest and misconduct activities (MND 2011), as well as it will ensure safe and security education to promote the strengthening of the quality of Human Life, and it will focus on sustainability, through appropriate awareness programs.

Agreeing with WWF (2017), the promotion of the “sustainability-stability-security” doctrine aims to “transform analyses and initiatives” of Policy and Military Forces “into concrete action for local population” to mitigate several harm consequences or exogeneous problems out of any individual’s control, for example, to divert attention from education on climate change, to prevent harm effects of rising sea levels, to protect from extreme weather events and water stress, to

avoid land degradation and desertification, to decrease the competition for natural resources, to reduce health hazards, and to help migrations demands. The Policy and Military Forces may be able to act on the defence of law and effective enforcement on the regulation that fight opaque order of the society and increase their reputation. It is imperative to promote vocational training within Policy and Military Forces, constituting one of the main pillars of sustainability. Beyond inequalities and inadequacies, the Military Service professionalization model may guarantee the transferability from the labor market of qualifications and skills acquired to the public service (MND 2018) to apply the same rules for all.

Following EU (2014a), the effective modalities and instruments of cooperation, in line with OECD best practice, include the use of innovative instruments, such as mechanisms for combining grants and loans. Participation of the private sector takes consideration of the debt sustainability, as the number of mechanisms and requirements for systematic impact assessment is, especially, in line with the goal of reducing the poverty level.

In this sense, another relevant activity of the policy and military forces sustainability is peace-building process. This process is dependent over the issue of local ownership between problem-solvers who believe that local ownership can “save liberal peace-building” and critical voices claiming that local ownership is purely a rhetorical device to hide the same dynamics of intervention used in more “assertive” interventions (Lemay-Hébert and Kappler 2016). The awareness of these processes is essential to the policy and military forces sustainability in terms of the emergence of new ideas, best strategies to live in society, and to enforce that the law is compiled by the Government.

Summary

Policy and military forces sustainability play an important role to prevent and to combat all forms of crime, because policies and military forces, created and management by the State, act on the public interest to reinforce the security of the

citizen and its goods. Therefore, sustainability can be seen as the model that each country and the State will enforce the citizen and the society to collaborate closely with all the stakeholders of the policy and military forces to ensure the most efficient and effective use of its security and military resources, creating a link to focus on the social, environmental, and economic perspectives. As public entities, the aim of integrating activities developed according to the internal security national policy of each country, in all dimensions in the force’s military and, in exceptional situations, in the field of national defense, emergency state, and defense of democratic legality, will demand and guaranty the citizens’ well-being.

Sustainability is implied in the policy as well as in the military forces around the world in order to ensure their financial stability with new solutions to fight against serious and organized crimes, democratic control, increased data protection, fight terrorism, and “including training, mentoring and advice on, for example, human rights, governance and the rule of law, the protection of women and children, civilian crisis response, human resources management and technical cooperation” (EU 2017).

The importance of these cooperation is indorsed by the Sustainable Development Goal (SDG) 16 that details “strengthen relevant national institutions, including through international cooperation, for building capacities at all levels, in particular in developing countries, to prevent violence and combat terrorism and crime” (EU 2017). Indeed, the promoting of peaceful strategies on the society through interact and reinforce SGD 16 as well as lead strong regulation and laws to achieve other development policy outcomes was underlined to fight economic, social, and financial crises, governance and policy failures, scandals, and excessively fragile environment sustainability, without undue delay, will provide guaranty to fulfil the European Agenda of the European Green Deal or in the 2030 Agenda for Sustainable Development, adopting the Resolution of the United Nations General Assembly (UN 2015).

Policy and military forces provide, also, the economic sustainability in terms of interoperability of activities, trust of the exchange information

from the digital information systems, and effectiveness and efficiency strategies which are essential to enhance the security and the development of the country. In this way, it is possible to conclude that Policy and Military Forces Sustainability is supported on the law enforcement of security and citizen well-being.

Politics (Role of Politics in Sustainable Development)

Alexandra Korcheva

Sofia University “St. Kliment Ohridski”, Sofia, Bulgaria

[Sustainable development politics](#)

Definition/Description

Achieving sustainable development is a long-term goal, where different stakeholders are engaged with the practical application and commitment to achieving the global sustainable development goals (SDGs), which were adopted by the United Nations (UN) in 2015 (Sachs et al. 2019).

Formally introduced on the 1992 Rio Earth Summit, the concept of sustainable development

has become a corner stone for political decision-making on both the global and local scale. However, despite having achieved advances from theory to practice, public sectors in countries around the world still struggle to find the optimal political solutions for adopting efficient sustainable development policies.

In taking the decision on adopting one or another policy, the decision maker often becomes entangled in the classic trade-off between adopting an immediate-return short-term solution and adopting a higher-return long-term solution. By applying tools tailored for serving the sustainable development transition, the political decision makers address the four components of sustainable development, namely, securing wealth creation, ensuring stewardship, empowerment, and realization of stakeholders on the sharing of a common future (O’Riordan and Voisey 1997).

Political decision makers have to figure out the optimal solutions for policies – how to balance the interests of different stakeholders, how to develop well-tailored regulations for specific markets, and whether to rely on society or impose rules in terms of adoption of sustainable practices (Hörisch et al. 2014).

The Sustainable Economy, the Social Development, and the Stakeholders

The politics of sustainable development requires balancing of the needs and preferences of a wide spectrum of stakeholders. Decision-making processes that require more intensive cooperation between stakeholders are more likely to result in higher-quality decisions (Beierle 2002).

Despite being a more intensive approach to making decisions about sustainable development policies, the stakeholder approach has been considered pivotal to political decisions in the sphere. The preference of this approach derives from the general tendency to involve a wider set of stakeholders in recent decades, as well as from the nature of sustainable development, which seeks the optimal solutions for achieving both the interests of business and that of society.

Hörisch et al. (2014) identify three main challenges of managing stakeholder relationships for sustainability, namely:

- Strengthening the particular sustainability interests of stakeholders
- Creating mutual sustainability interests based on these particular interests
- Empowering stakeholders to act as intermediaries for nature and sustainable development

To address these challenges, they suggest the application of a mechanism that features education, regulation, and sustainability-based value creation (Hörisch et al. 2014).

The stakeholder engagement approach to adopting policies for sustainable development led to the emergence of the so-called collaborative environmental governance (CEG) practices, where different stakeholders such as producers from various points of the supply chain, public authorities, researchers, and in some aspects consumers are engaged in a process of shared governance of ecological and social conditions. Recent research suggests that the stakeholders perceive a strong relationship between the established governance process and the effectiveness of governance in terms of outcomes (Lindgren et al. 2021).

A considerable amount of political discussion has been raised in terms of the relation of business with sustainability. Recent years have witnessed a rise in political incentives for the adoption of mechanisms that enhance the accountability and transparency of companies in the context of sustainable development. One such way has been perceived to be business reporting. In the EU, the political debate about the ability of non-financial reporting and providing stakeholders with useful and value relevant information about company behaviors resulted in the EU Directive 95/2014/EU (Phan et al. 2020). Recent research by Phan et al. (2020) shows that disclosing non-financial information by companies is still developing as a process and that it would take some more time before its advantages are fully appreciated. Research shows that this process is so far

best adopted by larger companies and/or companies with higher-risk profiles (Phan et al. 2020).

Political divestiture of sustainable development funding has been considered as an alternative means aiming at an innovative investment allocation to maximize positive development impacts of investment while achieving minimization of associated risks from politically insecure markets. Removing funds from politically incorrect regimes and channeling them toward socially responsible finance solutions need further analysis and development of the respective domestic and local institutional frameworks (Puaschunder 2016).

The politics of sustainable development have become an arena where emerging political actors have gained more political power in decision-making. The traditional political interactions between national interest groups have been contested by such emerging actors like global civil society and environmental nongovernmental organizations (NGOs) (Lafferty 2007).

Another tendency that has been recognized in the political process of sustainable development is the extinction of the firm boundaries between strictly national politics and international relations. More particularly, domestic issues concerning sustainable development and environmental protection have been internationalized through multinational nongovernmental organizations, international organizations (such as the agencies from the United Nations system), and various international cooperation forums such as the G8 and G20.

Despite political pressure to adopt sustainable development policies witnessing a significant rise, the adoption of such policies and practices on the national level has not been an easy task for policy makers. According to authors Tim O’Riordan and Heather Voisey (1997), the transition toward sustainable economies has to be assisted by a series of institutional changes which are not part of the UN sustainable development agenda. However, they confirm that there are distinctive features of sustainable development that clearly create important and continuing institutional change (O’Riordan and Voisey 1997).

Toward a Knowledge-Driven Policy-Making Process

Another trend in political interaction on the topic of sustainability has been the significant rise of the science-based decision-making approach. Environmental degradation due to human activity and climate change have both been topics of wide discussion among scientists in the last decades.

As it concerns topics where environmental impact is calculated based on scientific research, communicating scientific results to policy makers has become an important part of science in the context of sustainable development stewardship (O’Riordan and Voisey 1997). In this way, both scientists and politicians benefit, as the first get to promote their research in an efficient way and the second get to be provide with valuable information for knowledge-based decision-making (Safford and Brown 2019).

In the EU, closing the gap between science and other stakeholders such as citizens and civil society has been another important process that aims to drive European society to a knowledge-based social order and decision-making (EC 2020).

SDG Policies in Different Countries

The SDGs are 17 goals that have a total of 169 underlying targets that each country has to achieve by 2030 (OECD 2016). It is the precise targeting of different actions that makes it possible for organizations of both the public and private sectors to follow and implement certain actions and policies. With the development of the targets, measuring country advances toward achieving the SDGs was made possible. The SDG Index became a powerful instrument to observe policies and actions taken upon in each country (Sachs et al. 2019).

Developed countries that are members of the OECD and some Central and Eastern European countries lead the way into implementing sustainable development policies. According to the SDG Index Country Ranking, the country that

is performing best in achieving sustainable development and implementing SDG policies is Denmark (Sachs et al. 2019).

The commitment of countries to achieving the SDGs is split by the SDG Index analysts in three layers: high-level public statements by governments in support of sustainable development; strategic use of public practices and procedures for the goals (coordination mechanisms, budget, procurement, human resource management, data, and audits); and content of government strategies and policy actions (Sachs et al. 2019).

Looking upon sustainable development policies, it becomes clear that two trends in policy-making are established. The first trend is the focusing on the developmental goals (such as eradicating poverty and providing education) which is characteristic for developing countries and is associated with welfare economic policies. The second trend of policy-making is the sustainability focus, which is now more than ever associated with the concepts of green economy and green economic growth. This trend is followed mostly by more developed countries, and it has now become a part of the race for creating cutting-edge innovations and endogenous economic growth.

It is still very challenging for governments to implement policies that are more far-reaching and long run. Therefore, it is only logical that the SDG Index has that ranking, as there is definitely a path dependence in sustainable development policies, and countries that have a longer history of policy-making in this direction are certain to be natural leaders in the field.

However, as a recent report on sustainable development notices, even the most developed nations still have to pursuit the achievement of the SDGs, emphasizing on the importance of action and commitment from G20 countries, the lack of which would deprive large shares of the world population from sustainable development (Bertelsmann Stiftung and Sustainable Development Solutions Network 2019). Political decisions that are far-sighted and oriented toward the long-run are therefore proclaimed as more than necessary.

Summary

Implementation of sustainable development practices in both the public and private sectors requires a long-run strategic behavior by decision makers. More and more emerging stakeholders gain political power to ensure better decision-making in terms of adopting sustainable development policies. Key factor in the politics of sustainable development has become the scientific expertise provided by various disciplines as a foundation for a science-based policy approach.

With the SDGs as powerful tools for policy prescription, governments have now started to adhere to the needs of implementing policies that would ensure the reaching of the goals by 2030. The role of politics in achieving the SDGs is of highest importance, and it is considered that the SDGs cannot be achieved unless political will is present and expressed in relevant policies.

Pollution

Stefania Massari, Pier Paolo Miglietta,
Federica De Leo and Marcello Ruberti
University of Salento, Lecce, Italy

Synonyms

[Contamination](#); [Degradation](#); [Deterioration](#)

Definition

Pollution is an alteration of the environment by polluting elements, due to nature and anthropic activities. It produces temporary discomforts, pathologies, or permanent damage to living organism in a given area and can generate imbalance in the existing natural cycles. The alteration can be of various origins, chemical or physical.

Although some factors can be unequivocally considered pollutants, and their infinitesimal presence can be considered pollution, there is no substance or factor due to physical, chemical, and biological agents that is *a priori* polluting or non-polluting. It is the specificity and size of a circumstance that can be polluting.

Therefore, pollution includes everything that is harmful for life or significantly alters the physical–chemical characteristics of water, soil, and/or air, such as to change the health, the structure, and the abundance of living beings and/or energy flows, especially when it is not compensated by an adequate natural or anthropogenic reaction that delete the total negative effects.

Although there may be natural causes that cause unfavorable environmental alterations to life, e.g., fumes of a natural fire, or sulfurous exhalations of geological origin, the “pollution” concept generally refers to human activities.

Introduction

In theory all the anthropic activities and the built environment constitute pollution, as they interact with the natural environment, changing its original conformation. However, in some cases, the built structures can coexist harmoniously with the ecosystem, not altering the preexisting equilibriums in the natural environment or even contributing to preserve them.

In conclusion, the definition of pollution depends on the context, i.e., on the natural system taken into consideration and on the type of alterations introduced.

The increase in the anthropic activities has implied numerous transformations of the earth system. For example, the increase in the carbon

dioxide (CO₂) emissions has altered the natural carbon reserve cycle, which operates as an interchange between the various earth layers and the atmosphere. The exchange of carbon between the oceans and the atmosphere is already compromised, so that the increase in CO₂ that dissolves in the oceans makes the waters more acidic with negative implications for marine life. The balance of carbon exchanges between the atmosphere and terrestrial vegetation is still in equilibrium, but the indiscriminate deforestation also threatens this interchange. Meanwhile, the greenhouse gases (GHG) emission(see) into the atmosphere increases the natural greenhouse effect by increasing the global average temperatures causing the glacier melting, the thermal expansion of the oceans, the climatic alteration, and the increase of extreme climatological and meteorological phenomena with consequent hydrogeological instability (Vitousek 1994). The global effects of pollution require urgent ex-post interventions, but policy-makers are also addressing their efforts towards the pollution prevention (see).

Classifications

There are many types of pollution, divided according to the pollutant or the polluted element, with frequent mingling due to their contiguity or close correlation. Pollution classifications are therefore varied, but the two traditional categories include different types of pollution based on the polluted site and on the pollutant cause (Fig. 1).

Air pollution (see) refers to the presence of all the physical, chemical, and biological agents that modify the atmospheric natural characteristics and can cause a damaging effect on living beings and the environment. These agents are usually not present in the normal composition of the air or are present at a lower concentration level. They can refer to: nitrogen (NO_x), sulfur (SO_x), and carbon (CO_x) oxides; volatile organic compounds, in particular, mono- and polycyclic aromatic hydrocarbons, organic halides such as freons, ozone, free radicals, lead, and other so-called heavy metals, and particulates. The main sources of the release

Pollution, Fig. 1 Pollution classifications based on the polluted site and the pollutant cause. (Source: Personal Elaboration)

of pollutants into the atmosphere include industrial chemical plants, incinerators, motor vehicle combustion engines, and combustion in general (Daly and Zannetti 2007).

Water pollution consists of the contamination of water, rivers, lakes, and seas resulting from sewage or domestic, urban, chemical industrial, or nuclear waste spilled into the environment (Goel 2006).

Soil pollution consists, as for water pollution, of the contamination of soils deriving from sewage or domestic, urban, chemical industrial, or nuclear waste spilled into the environment (Mirsal 2008).

Indoor pollution is a type of pollution which develops in confined environments in the

presence of all the physical, chemical, and biological agents modifying the basic characteristics of the confined environment itself (Hänninen and Goodman 2019).

Domestic pollution refers to stale air, vapors, cigarette smoke, and chemical fumes inside homes. Even building and cleaning materials can be pollutant, causing harmful effects on the inhabitants, as well as poorly functioning air conditioning systems, electromagnetic fields, and radon infiltration (Hänninen and Goodman 2019).

Workplace pollution concerns occupational exposure to agents treated during work and represents the cause of occupational diseases.

Urban pollution is due to the concentration of pollutants in the air and to the urban characteristics, generally counteracted by the planting of tree species, which through photosynthesis can fix the CO₂ and store the excess as biomass (carbon sequestration), also helping to mitigate the air temperature (Tarr 1996).

Chemical pollution derives from chemical substances and/or mixtures spilled into the environment, often due to human, industrial, and agricultural activities, a potential danger to human health and the environment. Traces of heavy metals, for example, are normally present in the environment, but mercury, cadmium, and lead become potentially dangerous if they reach higher concentrations. Among the polluting chemicals, dioxins, used for the herbicide production, are the most toxic (Travis and Hester 1991).

Photochemical pollution is a form of pollution from chemical compounds whose formation is catalyzed by light (Altshuller and Bufalini 1971).

Noise pollution represents the set of negative effects produced by the noise present in the environments. Noise causes disturbing effects on man not only for the physical but also for the psyche, conditioning study, work, leisure, and sleep, and can cause ear injuries and partial or total hearing loss. Usually it creates a sense of tiredness, nausea, hypertension, nervousness, gastric disorders, headaches, difficulty concentrating and sleeping, and vertigo (Goines and Hagler 2007).

Electromagnetic pollution includes a multitude of polluting physical agents. It is linked to the presence of artificial electromagnetic fields that

is not attributable to natural events but to electric fields produced to transmit information through the propagation of electromagnetic waves from power lines, and from all devices operating through the electrical network (Rosen and Rinaldi 2000).

The pollution caused by plastic includes instead the dispersion and accumulation of plastic products in the environment. This type of pollution affects the air, the soil, the rivers, the lakes, and the oceans. The importance and relevance of this type of pollution derive from the cheapness of the plastic and its high durability over time and the enormous quantities used for the most varied uses.

Light pollution derives from light waves which disturb the perception of the environment or the natural physiological processes correlated with light (Hölker et al. 2010).

Thermal pollution refers to the increase of temperature in the environment; it can be caused either directly by anthropic activities which imply the release of heat into the environment or indirectly by the natural release of climate-altering gases.

Genetic pollution is attributable to the introduction of foreign living species, natural or not, including those created through genetic engineering processes, which often compete with natural ones and change the delicate interactions of the biodiversity (see ecosystems) (Hoyle 1999).

Radioactive/nuclear pollution derives from radioactive substances, radionuclides, or directly ionizing radiation (Busby 1995).

Architectural pollution refers to the alteration of the aesthetics and functionality of ecosystems and natural and urban landscapes. Constructions that do not meet the standards and the parameters established by the regulatory landscape plans are considered building abuses. The wrong placement of some buildings disturbs the habitat of the species, and alters the climate and the hydrogeological regime. It is considered an architectural pollution factor, even an architectural intervention that significantly changes the historical characteristics of a monument (Widanagamage 2011).

Agricultural pollution is caused by the incorrect and excessive use of fertilizers and pesticides. The latter, being water soluble, reach the aquifers, causing the water supply pollution; furthermore, not being completely biodegradable, they are deposited in water courses favoring the eutrophication process, which leads to the destruction of the present living forms (Merrington et al. 2002).

Industrial pollution is caused by the discharge into the ground, into the air, into the rivers, and into the seas of toxic substances, often non-biodegradable, which come from different processes and that can cause irreversible damage (Shen 1995). Some of these industrial substances are: cyanide, cadmium, mercury, and chromium. In industrialized cities, the sulfur dioxide (SO_2) is transformed into sulfur trioxide (SO_3) by activation of solar rays and subsequent oxidation, thus causing the precipitation of acid rain (see). As mentioned, the polluting substances of the industries also reach the waters of the rivers and seas, causing, for example, eutrophication, i.e., an excessive development of algae and the consequent death of the aquatic fauna due to anoxia caused by the rotting of death algae.

Summary

Pollution is an alteration of the environment by polluting elements, due to nature and anthropic activities. It produces temporary discomforts, pathologies, or permanent damage to living organism in a given area and can generate imbalance in the existing natural cycles. The alteration can be of various origins, chemical or physical. It produces temporary discomforts, pathologies, or permanent damage to living organism in a given area and can generate imbalance in the existing natural cycles, ecosystem equilibrium, and biodiversity. There are many types of pollution, divided according to the pollutant or the polluted element, with frequent mingling due to their contiguity or close correlation. Pollution classifications are therefore varied, but the two traditional categories include different types of pollution based on the polluted site and on the pollutant cause.

Cleaner production; Cleaner technologies; Integrated pollution prevention; Low and non-waste technologies; P2; Preventive environmental strategy; Reduction at source; Source reduction; Waste avoidance; Waste minimization

Definition

Pollution prevention (P2) is any practice that reduces, eliminates, or prevents pollution at its source. This covers the reduction of the amount of a hazardous substance, pollutant, or contaminant entering any waste stream or otherwise released into the environment. Pollution prevention is on the top of the environmental protection hierarchy prior to recycling, treatment, or disposal. The preventive approach to environmental issues is associated with developing the concept and practice of cleaner production in the early 1970s. The pollution prevention, cleaner production, waste minimization, and reduction at source are usually treated as synonyms. Pollution prevention uses many techniques that allow to eliminate waste at the source by modification of production processes, introducing nontoxic or less toxic substances or reusing materials rather than putting them into the waste stream.

Introduction

When pollution results in the production process, it means that the process is inefficient or is carried out carelessly. Pollution is really a loss for the company: valuable substances migrate to the sewage or escape into the atmosphere. Added to this

are fees for using the environment and often even penalties. The direct cause of environmental pollution is man-made production. The sources of waste are (Doniec 1998, p. 9) the production process itself (pollution is embedded into the way the manufacturing process is planned and organized), accidental situations during the process (accidents), careless leading of the production process, and the product itself after the period of use.

The first, in the historical sense, approach to the waste problem was do nothing (ignoring the problem). The creation of industry was not accompanied by the idea of the possibility of pollution and contamination of the human life environment. It appeared only when the negative phenomena began to be visible and troublesome.

When the substances escaping from industrial plants started to have too high concentrations on particular areas, a man came up with a very simple idea to spread the stream of these substances. According to this philosophy, water was added to excessively concentrated wastewater; higher chimneys were built, which resulted in the same effect: fewer pollutants per unit area. The symbol of this period was the high chimneys that surrounded human settlements (in artistic works they were praised as an example of a new beauty, even more perfect than the beauty of nature). The spreading policy of the waste stream did not change the size of the waste stream, and after some time, the problems returned on an increased scale.

There was no other choice than to begin to think what to do with the emerging pollution, because the previous solutions were insufficient. The focus was put finally to the waste stream – would it be possible to clean it up? This way, a whole new branch of industry was created associated with purification, producing sewage treatment plants, filters, and other devices installed in industrial plants. Due to the place of installation of these devices, solutions based on purifying the stream of pollutants were called end-of-pipe solutions. In the organizational sense, they have one undoubted advantage: they require only to purchase of a ready device. However, their disadvantage is the cost – both of the purchase and operational cost too. Many people still equate

environmental protection with cleaning approach and, consequently, with the costs of such kind of environmental protection policy.

Instead of wondering what to do with waste that has already been created, it is better to try to prevent it from creation and thus concentrate on the causes of problem. This preventive approach works, and even due to its effectiveness, it is being promoted and required by counties' legislations. Its ideal purpose is a completely waste-free production process. In practice, of course, any effective reduction of the pollutant stream or limiting its toxicity is sensible and desirable. Techniques for preventing environmental pollution are becoming more and more popular as a long-term strategy for environmental protection, because their use is profitable (as opposed to expensive cleaning techniques). Every reduction in the amount of waste generated translates into savings in the consumption of raw materials and energy.

Pollution Prevention Approach

“Pollution prevention (P2) is any practice that reduces, eliminates, or prevents pollution at its source” (U.S. EPA 2019). That is why it is also known as “source reduction” and is the essence of a preventive approach to waste management. This covers the reduction of the amount of a hazardous substance, pollutant, or contaminant entering any waste stream or otherwise released into the environment.

Pollution prevention (P2) and thus the preventive approach to environmental issues is associated with developing the concept and practice of cleaner production in the early 1970s (Rodhe 2000, p. 18). The main idea behind the preventive approach is that all actors (industry, government, and consumers) should take the increased responsibility for the process of reducing environmental impact.

The preventive strategy integrates the environment in the global management of the organization. “Its application requires responsible environmental management, a change of attitude

and the evaluation and application of technological knowledge and options” (SCP/RAC 2019). “The preventive approach has many parallels with quality management, including the idea of doing things right from the start, the need for employee participation, the need for integration in company-internal processes, and continuous improvement using the plan-do-check-act cycle” (Rodhe 2000, p. 20).

The preventive approach demonstrated by organizations is usually organized in the form of continuous internal integrated programs or even applied as an element of the management system (e.g., Environmental Management System ISO 14001 or Eco-Management and Audit Scheme – EMAS). Such an approach (program or procedure) usually consists of the following phases (Rodhe 2000, p. 24):

1. Planning and organization
2. Assessment
3. Feasibility analysis
4. Implementation

The whole process should be repeated continuously.

When different actions toward the cleaner environment are considered, the pollution prevention is on the top of the environmental protection hierarchy.

Exemplary environmental protection hierarchy (U.S. EPA 2019):

1. Pollution prevention (source reduction)
2. Reuse
3. Recycling
4. Treatment
5. Disposal, release

The higher on the list, the more preferable particular practice is. P2 is very often contrasted with the end-of-pipe treatment.

Pollution Prevention Techniques

Pollution prevention uses many techniques that allow to eliminate waste at the source by

modification of production processes, introducing nontoxic or less toxic substances or reusing materials rather than putting them into the waste stream. It means less waste to control, treat, or dispose.

The four categories of techniques are available to organizations when implementing P2 approach (IISD 2019):

1. Good housekeeping – including efficient operation of machinery, monitoring of raw material flows, segregating waste, and training staff
2. Materials substitution – such as phasing out CFCs and switching from solvent-based paints to water-based alternatives
3. Manufacturing modifications – including cutting the number of processes or switching from chemical to mechanical and introducing closed-loop processing
4. Resource recovery – for example, reusing pollutants in the same process and selling waste by-product as raw materials in other industries

Pollution prevention is not just only about reduction of the use of hazardous materials but energy, land, and water too. When choosing the pollution prevention options, one should care about the elimination or reducing waste released rather than just transferring or distributing pollutants among the land, air, and water (NOAA 2019).

Pollution Prevention Benefits

Unlike most pollution control strategies, an effective, ongoing P2 program offers important economic, regulatory, environmental, and social benefits that can often result in a more competitive business (IN.gov 2019). By increasing the efficiency, companies achieve not only significant environmental effects but also economic effects. Increasing the efficiency of production processes, savings on the costs of using the environment, savings on raw materials and waste flow management, and treatment mean money that will remain in the enterprise. In addition, enterprises can gain market recognition and attract new partners and customers, especially when they can demonstrate

a cleaner production leader certificate or certificate of the Environmental Management System. The list of potential benefits from the pollution prevention can be very long and include also (U.S. EPA 2019; NOAA 2019; SCP/RAC 2019):

- Safer working conditions
- Better quality of the product, fewer products which do not conform to specifications
- Less hazards posed to public health and the environment
- Less need for households, businesses, and communities to handle waste
- Reduction of risk of industrial accidents and spills
- Improvement of corporate image
- Fulfilment of the company's environmental requirements and a commitment to its sustainable development

Due to its benefits and effectiveness, the preventive approach was introduced to legal regulation in many countries (e.g., in the USA, Congress passed the Pollution Prevention Act in 1990). The national agencies were required to implement the pollution prevention program, to promote this approach both in terms of dissemination of information and financial support for individual projects of cleaner production (U.S. EPA 2019). The pollution prevention was a subject to many promotional activities on the international arena (e.g., by USAID, UNEP, or Government of Norway).

Summary

Pollution prevention is the approach to waste management that concentrates on the elimination or the reduction of the waste stream. This means both reducing the amount of wastes but also the toxicity of the waste stream. Many countries introduced the pollution prevention to their legislation and environmental policy promoting its benefits among companies. The typical pollution prevention techniques can help organization to solve its environmental problems and bring savings at the same time.

Porter and Kramer's (2006) "Shared Value"

Maria Roszkowska-Menkes
Department of Management Theory, Warsaw
School of Economics, Warsaw, Poland

Synonyms

Strategic CSR

Definition

The Creating Shared Value (CSV) concept focuses on "policies and operating practices that enhance the competitiveness of a company while simultaneously advancing social and economic conditions in the communities in which it operates" (Porter and Kramer 2011, p. 6). Its authors, Porter and Kramer, suggest that social needs, similar to more traditional market needs, define markets and create business opportunities, while social harms are not always externalized by the company, but often create internal costs, e.g., wasted energy, raw materials, costs related to on-the-job accidents or high employee turnover. Thus, it is not only desirable but, more importantly, possible to form business strategies that lead to the creation of social and economic values at the same time. By value, the authors mean not just benefits, but benefits relative to costs. Although the idea of value creation has long been recognized by business, social progress was rarely approached from this perspective. The notion of value was based rather on short-term financial gains with social issues treated as peripheral to core business. With their conceptual framework, Porter and Kramer hope to "redefine the purpose of the corporation" and "reshape capitalism and its relationship to society" (Porter and Kramer 2011, p. 4). The authors assume that the new purpose of a business constructed around shared value and not just profit has the best chance to rebuild trust and the legitimacy of the business.

CSV has emerged on the wave of increasing criticism of corporate social responsibility (CSR), which is more widely viewed as an empty promise, a mere response to anti-corporate movements, an egoistic exercise, and even a passing fad (Mullerat 2010, pp. 443–452). As an alternative concept, CSV has received attention and positive feedback in the business community, which finds it very appealing, as well as among some management scholars and teachers (Crane et al. 2014). The shared-value approach to business and society relations also has been recognized by the European Commission and incorporated in the new CSR definition as a concept through which companies voluntarily integrate social, ethical,

and environmental concerns into their business operations and core strategy in close cooperation with their stakeholders with the aim of, one, identifying, preventing, and mitigating possible adverse impacts in these areas, and two, maximizing the creation of shared value for their owners/shareholders and for their other stakeholders and society at large (COM 2011).

Porter and Kramer's Criticism of CSR

Porter and Kramer (2011) argue that the more companies have become engaged in CSR, the more its legitimacy has fallen. The authors' criticism relates to the way CSR is understood and implemented in business practice. Companies have remained trapped in an outdated and narrow approach to value creation focused on optimizing short-term financial performance and ignoring environmental and social drivers of the firms' long-term success. Further, the authors point out that the dichotomy between social and business interests has been strongly institutionalized in the CSR concept itself. The classical approach to CSR has been based on a deontological perspective focusing on profit-sacrificing activities motivated by social altruism (Horrigan 2010, pp. 34–35). Within this approach, CSR has been defined as "situations where the firm goes beyond compliance and engages in actions that appear to further some social good, beyond the interests of the firm and that which is required by law" (McWilliams et al. 2006) (see ► ["Altruistic CSR"](#)). The separation of business goals and societal needs, as argued by Freeman and McVea (2001), led to the marginalization of CSR in the eyes of many managers and scholars. As a result, "most companies remain stuck in a "social responsibility" mindset in which societal issues are at the periphery, not the core" (Porter and Kramer 2011, p. 4). Some critics assert that although the CSR concept is built on good intentions, corporate leaders often misuse it to produce benefits only for their firms (Yunus 2007). Business has co-opted the language of social responsibility to allow it to continue to focus almost single-mindedly on profit maximization

(Horrigan 2010, p. 35). Fleming and Jones (2013) argue that what has come to be called "corporate social responsibility" has become a key marketing and branding tool for most large and medium-sized companies. Many activities in the area of CSR are accompanied by hypocrisy on the part of the companies and are mere attempts to contain civil pressure. Porter and Kramer (2006) note that in many companies, CSR is limited to cosmetic actions, centered on glossy reports of questionable credibility (Broomhill 2007). CSR has been widely used as a PR or even whitewashing tool (Faust 2006), or as a strategy for avoiding regulation (Mullerat 2010, pp. 448–449), leading to a substantial decrease of trust among stakeholders.

Porter and Kramer (2011) argue that CSV as an approach integral to a company's competitive position should supersede reputation-driven CSR in guiding corporate social and environmental investment. The proposed concept is hoped to open up new opportunities for innovation and growth in global economies, become the next evolution of capitalism, and help companies regain legitimacy.

The Emergence and Evolution of the CSV Concept

The concept emerged from a series of articles by Porter and Kramer for the *Harvard Business Review*. The first of the papers, published in 2002 (Porter and Kramer 2002), focused on **strategic corporate philanthropy** as an answer to the dilemma faced by many executives caught between critics demanding ever higher levels of donations and investors' expectations to maximize short-term profits. Corporate charitable efforts limited to small donations generating no social value and ad hoc actions or cause-related marketing and sponsorship campaigns used as a popular branding tool have become the subject of broad criticism from both civil society and shareholders. The authors argue that corporations can use philanthropy in a strategic way, as an investment to improve their competitive context, understood as the quality of the business environment. In this way, companies are able to integrate social

and economic goals and drive their long-term competitiveness, and by leveraging their core competences, generate virtual social change.

In the second article in the series (Porter and Kramer 2006), where the term "shared value" was coined, the new approach to corporate philanthropy was extended to the integration of other CSR activities into the core business strategy. Although companies recognized the growing stakeholder pressure for more responsible business conduct, their response has been limited to cosmetic actions focusing largely on public relations and media campaigns. In a world of open, knowledge-based competition, social and business goals form a symbiotic relation (Porter and Kramer 2006); "CSR and competitiveness are not opposed but rather link in a synergic relationship" (Perrini et al. 2006, p. 6). Thus, the distinction between these elements is a false dichotomy (Porter and Kramer 2002). This mutual dependence in business-society relations implies that both business decisions and social policies must follow the principle of shared value and engage in strategic CSR activities. The latter focus on value-chain social impacts and social issues influencing a company's competitive context.

Finally, in 2011, Porter and Kramer (2011) published their seminal article offering a more substantial conceptualization of CSV. First, the authors proposed the definition of shared value as "policies and operating practices that enhance the competitiveness of a company while simultaneously advancing social and economic conditions in the communities in which it operates" (Porter and Kramer 2011, p. 6). In other words, not only must the shared-value strategies support core business objectives – a postulate often raised in previous publications on strategic CSR (Lantos 2002; Husted and Allen 2007) (see ► "Strategic CSR") – but also meaningfully contribute to social progress. What is more, as shared value is defined as benefits relative to costs, the concept focuses on maximizing social impact per dollar spent (Spitzeck and Chapman 2012). Second, the paper outlined mechanisms of shared-value creation (explained below). Each requires concrete and company-specific metrics. Successful CSV strategy is "data-driven, clearly linked to defined

outcomes, well connected to the goals of all stakeholders, and tracked with clear metrics."

An additional contribution to shared-value research has been made by Pfitzer et al. (2013), who identified five reinforcing elements that companies creating shared value rely on: (1) embedding a social purpose, i.e., setting and communicating a clear social mission that is integrated with the corporate culture of the firm, (2) defining a social need the firm can address by gaining a deeper understanding of the underlying social conditions, (3) measuring shared value, for example, through integrated reporting (Adams 2015), (4) creating the optimal innovation structure, for example, by integrating with current firm units, creating semiautonomous units, getting support from governments, or funding external businesses (5) cocreating with external stakeholders, such as other companies (including major competitors), universities, foundations, NGOs, and governments.

Creating shared value requires a close link between CSR activities and core business strategy (Husted and Allen 2007). On the one hand, it allows a firm to use its unique resources and competences, which increases the efficiency and effectiveness of social programs. On the other hand, it stimulates the development of new resources that may become part of the organization's competitive advantage.

CSV Mechanisms

There are three mutually reinforcing mechanisms of shared-value creation: (1) reconceiving products and markets, (2) redefining productivity in the value chain, and (3) enabling local cluster development (Porter and Kramer 2011). The first one is based on enabling local cluster development aimed at improving the company's competitive context. CSR is seen here as a social investment or strategic philanthropy (Porter and Kramer 2002) that improves: (1) access to high-quality business inputs (e.g., highly qualified employees, efficient infrastructure, access to research institutions, relevant technology, and capital); (2) demand conditions (e.g., by

increasing the size of the market or sophistication of demand); (3) strategy and rivalry context or, in other words, rules and incentives that govern competition (e.g., transparency, intellectual property protection, fair and open local competition, rule of law); (4) availability of supporting industries (e.g., reliable local suppliers, service providers, presence of clusters) (Porter and Kramer 2006). One example of CSV programs that aim at developing local clusters are corporate initiatives focused on education. Providing support to universities to build a strong base of highly qualified staff is less expensive than investment in in-house training. Success in tackling social and environmental issues involving cluster development often requires collaboration with third parties, including other companies (Porter and Kramer 2011).

The second mechanism of shared-value creation focuses on the redefinition of productivity in the value chain to depict all activities that a company engages in while doing business. The value chain can be used as a holistic framework to identify positive and negative social impacts in terms of energy use, logistics, resource use, procurement, distribution, location, and employee productivity (Porter and Kramer 2006). Opportunities for CSV may occur from process innovation that helps to reduce internal costs inflicted by externalities connected with poor management of natural and human resources. Reduction in GHG emissions, use of renewable raw materials, reduction of product packaging, cooperation with local suppliers, investment in the health and safety of workers, or diversity in the workplace serve as examples of initiatives leading to the simultaneous reduction of social and business costs. Major improvements in social and environmental performance not only can often be achieved with better technology at a nominal incremental cost but also can yield net cost savings through enhanced resource utilization, process efficiency, and quality (Porter and Kramer 2011).

The last mechanism enables reconceiving products and markets. CSV broadens the firm's perspective and helps to identify unmet social needs. In this sense, it creates opportunities for differentiation (Spitzeck and Chapman 2012), product and business model innovation, and

growth (Porter and Kramer 2011). What is more, the shared-value approach offers greater gains for society, as companies have the potential to be more effective than governments and nonprofit organizations in marketing solutions to social problems. As companies look for opportunities for innovation, Porter and Kramer (2011) suggest thinking in terms of societal needs instead of "products" and "services." Social and environmental issues increasingly define markets in developed economies, where conscious consumers make decisions based not only on price but also on sustainability-related attributes of products and services. Additionally, societal needs create business opportunities in emerging markets, where the greatest global growth potential is concentrated (Tidd and Bessant 2011). The majority of consumers in these markets form the so-called "base of the pyramid" (see ► "Base of the Pyramid" and ► "Prahalad's 'Bottom of the Pyramid'"), i.e., "the low-income socioeconomic segment" (London and Hart 2011, p. 8) that, due to the growing income gap between rich and poor, is not well integrated with the global market economy. The base of the pyramid is believed to represent a multitrillion-dollar market full of underserved social needs (Prahalad 2006).

Criticism

Although the CSV concept has gained much of the attention from both practitioners and academic community, it has also become a subject of criticism. Crane et al. (2014) identify four major weakness and shortcomings of CSV. First, the authors argue that the concept is based on unjust criticism of CSR. Porter and Kramer contrast CSV with an outdated understanding of CSR and do not acknowledge there is broad consensus in the existing literature that CSR is not a supplement to core business strategy but rather an integral element (Beschoner and Hajduk 2017). Second, CSV is based on a win-win assumption about business-society relations and as such does not provide any guidance for situations in which a win-win solution cannot be reached and moving beyond trade-offs

between social and economic value creation is impossible. Porter and Kramer are criticized for grounding their arguments in purely economic logic and arguing that the primacy of profit maximization is not only necessary due to market forces but also morally good (Beschoner 2013). Some authors argue that given the complexity of social issues, which usually involve a number of different stakeholder groups with conflicting interests, strategic CSR concepts, including CSV, will only reinforce neoliberal logic (Brown and Dillard 2014; Thomson 2015). Third, CSV is built on the controversial assumption that business compliance with legal and moral standards is given. The concept neglects the fact that the absence of compliance is one of the key problems of multinational corporations operating in various countries often with extremely poor regulation and in complex supply chains that are hardly possible to be fully controlled. Fourth, the CSV concept is strategically incoherent. CSV aims at creating additional profit opportunities and differentiating the company from its competitors. However, generating virtual social change requires multi-stakeholder cooperation and the creation of standardized solutions that could be scaled up across organizations, sectors, and countries and, as such, cannot be a source of competitive advantage for a single company.

Synonyms

Status good

Definition/Description

Positional goods are defined by Fred Hirsch as goods whose value for the consumer depends more on how these goods compare with the

goods consumed by others rather than on their direct utility. According to Hirsch, as the level of average consumption rises, so does the relevance—though also the negative side effects—of positional consumption (Hirsch 1976).

Hirsch defines a so-called positional economy which is different than the economy driven by standard neoclassical assumptions (Hirsch 1976). The material economy relies on assumptions for value creation that are driven by agents' rational behavior, so if production of goods is increased without loss of quality of the product, then the price of the product will be changed only through the adjustment of supply and demand to a new equilibrium point (Hirsch 1976). In the positional economy, people's relative position is measured by the access to and ability to acquire possession of goods that are scarce due to the effect of social competition. If a good becomes affordable to more people, it loses its value. Competing for works of art, good jobs, leadership positions, or luxurious leisure are examples of goods that are positional (Hirsch 1976).

Positional goods are often considered to derive their value if they are a factor that distinguishes their owner as a member of a social group in a favorable position in society. They are often associated with Thorstein Veblen's concept of conspicuous consumption (Veblen 1899/1994). A concept that is closely associated with the positional goods idea is also Robert Frank's notion of positional externalities (Frank 2011).

The Conceptual Framework

Fred Hirsch refers to a duality of economic growth, with positional economy opposing to material economy (Hirsch 1976). The main argument stems from the idea that there are goods in the economy which are offered to all, but few can afford. These goods therefore gain an additional social status value—they become signals to the prosperity of the people who own such goods. These social status value goods are coined by Hirsch as "positional goods" (Hirsch 1976, p. 25). As Koutsobinas put it in his book *The Political Economy of Social Status*, it is not only mechanical market exchange that drives economic change, but people's psychological

tendencies towards exclusive goods that are highly valued by others (Koutsobinas 2014). Economist Vatiero defined positional goods as both a double rival and double excludable good (Vatiero 2011). Other definitions of positional goods, such as the one given by economist R. Mathews, have related them to a function of individual income relative to other people's income (Schneider 2007). Positional goods are often associated with the concept of the "superstar phenomenon" of economist Sherwin Rosen (Rosen 1981).

From Hirsch's seminal work which was issued back in 1978 to present days, positional goods and their role in economic life has been widely examined. Status goods are considered to appear in homogenous markets and are distinct from regular goods with the fact that they become more sought after by consumers as their price rises (Koutsobinas 2014).

The positional economy is related to all aspects of goods, services, work positions, etc. that are either considered scarce in an absolute or socially imposed way or are subject to congestion or crowding when there is more extensive use of the goods, and as a consequence of crowding the perceived value of the good falls (Koutsobinas 2014). This distinction between positionality of goods is also regarded as vertical or horizontal positionality—with goods of competition being considered to have vertical positionality, and goods of coordination having a horizontal positionality (Hollis 1984).

Upon trying to define which goods are more positional than others, economists have established that the more visible a good is, the more positional it is considered (Carlsson et al. 2007). In this sense income is found to be more positional than leisure (Carlsson et al. 2007), as the value of automobiles is more positional than the safety of the car model that is implied.

Conspicuous Consumption

The positional economy and the somewhat innate (natural) inclination of people towards social status value have its roots in history of mankind and can be viewed from an anthropological point of view. Positional goods can be regarded as the tail

of a peacock or the colors of male birds in nature—features with no practical meaning except demonstration of power, social status, and biological advantage over competitors (Veblen 1899).

Conspicuous consumption supposes that the consumer buys some good because it is associated with some type of exclusivity. The term is coined by Thorstein Veblen in his 1899 work *Theory of the Leisure Class* (Veblen 1899). Veblen states that “conspicuous consumption of valuable goods is a means of reputability to the gentleman of leisure” (Veblen 1899, p. 36). The positional goods concept is situated in the foundation of theories in economics that assume social status is a key factor for consumer’s decision-making. Social status–driven decision-making of the individual consumer has an actual impact on aggregate demand and prices of goods. A hypothesis that researchers have endorsed is that visible goods are more positional than less visible goods (Carlsson et al. 2007; Frank 1985).

Positional Externalities

In Frank’s wording, a positional externality “occurs when new purchases alter the relevant context” (Frank 2011, p. 1). A typical example of positional externality that Frank gives is when some of the candidates for a job begin to wear expensive custom-tailored suits at job interviews, then a side effect of their action will become that other candidates become less likely to make favorable impressions on interviewers. Based on experiments, Frank postulates that within limits, people appear willing to sacrifice absolute consumption for improved relative position (Frank 2011).

Positionality creates patterns of behavior that are associated with the so-called “expenditure cascade,” which refers to the increase in expenditures by top earners resulting in increased expenditures even among those consumers whose incomes are not as high and have not risen (Frank 2011).

Effects on the Economy and Importance for the Public Sector

Analyzing economies, studies have shown that positional goods have a significant share of

consumption. According to Frank (2005, p. 137), “the conflict stems from the fact that concerns about relative consumption are stronger in some domains than in others. The disparity gives rise to expenditure arms races focused on positional goods—those for which relative position matters most. The result is to divert resources from non-positional goods, causing welfare losses.”

Positional goods equilibrium diverges from standard public goods equilibria where the rational incentive is considered to be the free-rider strive to contribute nothing or least amount possible. In the positional economy, status-seeking may counterbalance the free-riding incentives public goods provision if the positional preferences are sufficiently high (Bougherara et al. 2019).

Identifying positionality of goods has been suggested for policy prescription. Identifying positional goods has been proposed to serve as a tool for taxation policy measures—for example, if a good is highly positional, it may imply higher or more progressive taxes (Carlsson et al. 2007).

Positional economy rationality has been investigated in relation to public goods provision as well. Under certain conditions—for example, when positional preferences of individuals are homogeneous, then the individuals will tend to overinvest in the public good compared to equilibrium with no positional preferences, resulting in a zero-sum positional race with a higher public good provision. When agents have heterogeneous positional preferences, the overall impact on social welfare is positive when endowments are homogeneous (Bougherara et al. 2019).

Positionality of goods is often assumed to be relevant for more affluent societies, and more often analysis is oriented towards developed countries. However, it is in more recent years that the idea that there is a positional economy in every country—no matter a developed or a developing country—is gaining popularity, with policy prescription inspired from the positional economy of developed countries being on the rise (Koutsobinas 2014).

Summary

The positional economy is considered a concept that hard to measure, and for that reason it is still hard for economists to establish its actual size. However, it becomes more apparent in recent years that positional goods actually influence economic relations not only on the microlevel, but most likely on the meso- and macrolevels as well. The degree of positionality of a good is often considered to stem from social conventions and interactions rather than pure economic rationale of decision-makers, therefore the concept of positional goods is providing a bridge between the disciplines of economics and psychology.

Postgrowth

Rudi Kurz
Pforzheim Business School, Pforzheim
University, Pforzheim, Germany

Synonyms

De-growth; Delinking; Development; GDP (gross domestic product); Green growth; Growth paradigm; Growth policy; Innovation; Limits to growth; Stationary state; Transformation; UN SDGs (UN Sustainable Development Goals)

Description

Economic growth is the core idea of economics and is dominating all fields of economic policy on a global scale. Critique has been formulated since the 1970s and today evidence is overwhelming that growth and environmental goals are incompatible. Therefore, the challenge especially for advanced rich nations is to present a new model for long-term development. In the postgrowth era, growth will no longer be the dominating goal. Development and structural change will continue, however restricted by environmental guardrails. The core idea of the postgrowth era is “sustainable development.” This has far-reaching consequences and a “great transformation” is required. The transformation process can partly be designed (political reforms) and is partly the result of an evolutionary search and discovery process. The basic political challenge is to replace the promise of permanently increasing income and consumption by other contributions to good life, that is, socio-economic reforms and social innovations so that overall wealth and happiness will not decline. Only if these two processes – GDP decline and socio-economic innovation – work simultaneously, conflict potentials are low and acceptance is high. The transformation to the sustainable postgrowth age is a fundamental cultural and institutional change which affects all fields of life and policy: consumption patterns, work-life-balance, role of government (social safety and redistribution, public goods), innovation (productivity, obsolescence), companies’ business models, unions’ mission. Overall, neither economics as a discipline nor economic policy is well prepared for the postgrowth era and the dramatic transformation processes.

Dominance and Decline of the Growth Paradigm

Rise and Dominance

The idea of economic growth started to dominate economics and economic policy after WW II. In economics the theory of economic growth emerged as a rapidly expanding new field of

research (with pioneering work by E. D. Domar, R. F. Harrod, R. M. Solow) which crowded out the focus on crisis and business cycle. Policy was dominated by cold war and system competition – and out-growing the competitor became crucial. Since then growth has conquered center stage (see Dasgupta 2007; Schmelzer 2016).

Economic growth was attractive as it promised so many advantages: higher incomes for all (overriding distributional conflicts), more jobs (full employment), more government revenues (financing public goods, welfare state, and arms race), catching-up for poor countries. And even when the environment problems became obvious the answer was “growth,” that is, fast modernization of industry, high incomes to finance more environment-friendly solutions (“get rich first, clean up later”; Environmental Kuznets Curve). As economic growth seemed to be without cost, it was rational to exploit the benefits. Once “growth” was established as the top priority, all policies had to pass the test of growth compatibility – from infrastructure and education to energy and environment (e.g., OECD program: “Going for Growth”, <http://www.oecd.org/economy/going-for-growth/>). On a global scale, the growth policy dominance (imperative) has been imposed on developing nations by World Bank and IWF in form of the “Washington (growth) Consensus” (Dasgupta 2007, p. 27).

Critique and Decline

Critique of the growth paradigm started early (see, e.g., Boulding 1966) and had a first highlight with the report “Limits to Growth” by the Club of Rome (Meadows et al. 1972): “If present growth trends ... continue unchanged, the limits to growth will be reached within the next one hundred years.” Consequence: “Sudden and uncontrollable decline in both population and industrial production.” Many other critical reports and publications followed (e.g., Daly 1996; Stiglitz et al. 2009; Jackson 2009; Latouche 2010). But all this had little impact on the dominance of the growth paradigm. It triggered reforms to avoid some of the most obvious damages (e.g., water and air pollution, waste management). Such end-of-pipe policies made production slightly more expensive

but never where a threat to the growth paradigm. The corrections which have been made recently are labeled “green growth” (see OECD 2011), delinking growth of output from growth of resource input. “Green growth” has also been a reaction to the World Financial Crisis of 2008, which has shattered the credibility of unrestricted growth policy.

The most fundamental critique of the growth paradigm was that it is not possible to “generalize” this idea. If applied by all nations, the limits of the planet will be surpassed with dramatic consequences for mankind (Meadows et al. 1972; Olson 1973). Therefore, the “catching-up” promise for developing countries (based on higher growth rates) collapsed and the search for a new development paradigm began, a paradigm which could be generalized for all nations and also respects the basic rights of future generations. The process of global reflection on intragenerational and intergenerational justice produced as one important output the Brundtland definition of sustainable development (WCSD 1987): Fulfill the needs of the present (especially the needs of the poor) without shifting burdens on future generations (especially by overburdening essential eco-systems).

This is now formulated in the form of binding and ambitious sustainable development goals like the UN SDGs (2015) and the Paris Agreement on climate change (2015). This has shifted political priorities. The IPCC Report (2018) and the IPBES Report (2019) contributed to increase political awareness and activities significantly. Extreme weather conditions, interpreted as herald of climate change, and biodiversity loss (bees, insects) made it visible and clear to millions: business as usual is no longer an option – and this includes ever expanding production and consumption.

Also, over the last decade, growth has turned “uneconomic” (Daly 2014) and unattractive, basically because growth no longer delivers its initial promises:

- When the level of income is already high, more income does not contribute much to further increase peoples’ happiness (well-being). Are there more attractive ways to increase happiness?

- Growth is a win-win-strategy, however, some win more and distribution (of income and wealth) is perceived unfair (not enough trickle-down). Instead of being a “social mollifier,” growth delivers ammunition for social conflict.
- Growth comes with new technologies and (eco-)efficiency increases. However, the size of eco-efficiency increases is not enough to compensate the growth effect.

The end of the growth era is an “inconvenient” diagnosis (“truth”) as it will rock the material and the ideological fundamentals of society. The socio-political consensus within our societies as well as globally was based on the promise and perspective of a rising tide that lifts all boats. This has been the social glue (upward mobility) and global perspective (catching-up). As it is vanishing, what could replace it as a “social mollifier”? Is the shared value base and are institutions strong enough to manage the transition without disaster (system resilience)? Much will depend on economics as the discipline which invented and promoted the old outdated “growth paradigm.” Will this discipline be able to provide an alternative and useful advice for managing the transition period?

Growth Fading Away? (De-growth)

There is a wide-spread fear (even) in rich countries that growth drivers might dwindle, inherent dynamics of capitalism (competition and innovation) is lost and that the promise of ever increasing income and wealth no longer holds (e.g., Gordon 2016). Long-term growth trends reflect declining growth rates in almost all countries and benefits of growth are concentrated on a small group at the top. The widespread and diverse debate on system-immanent forces that might end the growth era includes factors such as:

- Innovation/technological progress weakens
- Aging population (tends to be less innovative)
- Nationalism (anti-globalization)
- Productivity growth decline
- Redistributive policies over-burden the rich entrepreneurial class (negative incentive effects)

- Increasing welfare state (consumption instead of investment)
- Work-life-balance (less willingness to work hard)
- Decay of infrastructure (complementary to private investment)
- Monopolization (stifling competition)

Additional barriers result from environmental SDGs and changing lifestyles (sufficiency) which could stop economic growth or turn it negative:

- Decarbonization will end of fossil energy consumption, dematerialization requires the reduction of material flows, and protection of biodiversity will restrict land use.
- Population will (has to) decline; sufficiency reduces labor market participation.
- Capital stock (industry, buildings, infrastructure) declines in transformation process as stranded assets increase.
- Technological progress will focus more on eco-efficiency instead of labor productivity.
- The sufficiency trend reduces consumers' demand (with negative effects on firms' investment) and leads to "secular stagnation" (Summers 2016).

Randers (2012) uses the following simple "forecast model":

$$\text{GDP} = \text{GDP}/\text{worker} * \text{worker}$$

With declining (and aging) workforce (working hours), growth depends on (increasing) labor productivity. If this also stagnates (aging, service economy), growth phases out, the economy is converging towards the "stationary state" (Mill 1848; Keynes 1930).

In sum: The traditional expansive forces of innovation, ingenuity, and effort will continue to be strong drivers of economic growth. In addition, governments promise to rekindle growth by "whatever it takes." However, it would be naïve and over-optimism to hope that growth will prevail forever. It is wiser to be prepared for an age without growth – and it is the job of economists to analyze to

consequences and to deliver the new concepts for stabilizing economy and society, especially resolving distributional conflicts in the absence of a growing cake. The minimal consensus now seems to be to make economies less growth dependent. In case of (exogenously) declining growth rates, society has to be prepared mentally, institutionally and physically (infrastructure). This would increase stability of society (resilience), reducing the success chances for radical political parties. Social stability should not be put to the test, instead preparations for the no-growth-world should be intensified (pension systems, etc.).

From Growth to Sustainable Development

Contradiction: Growth Versus Environmental Goals (De-growth)

Environmental sustainable development goals are defining limits to the use of environmental resources (impact I). Most prominent example (fixed in the Paris Agreement 2015): In order to stop climate change (temperature increase), CO₂-emissions have to stop by mid-century (decarbonization).

Economic growth is measured as increase of real GDP. GDP represents the value of all end products in one year and "real" means that price effects (inflation) are eliminated. There is a huge literature on the critique of the GDP concept and on the mismeasuring which it induces. And many proposals have been made to correct and to add (see Stiglitz et al. 2009). In fact, the GDP concept has been developed as a tool of output measurement. It was never been intended as an indicator for wealth. If at all, GDP/capita might serve this function.

The relation between impact I and GDP growth can be illustrated by a simple decomposition:

$$I = I/\text{GDP} * \text{GDP}$$

I/GDP is eco-efficiency, that is, environmental impact per unit of GDP. If I/GDP declines, I can decline – even if GDP grows.

Example: 2% p.a. GDP growth rate would increase the GDP by roughly 50% in the period 2020–2040. If the environmental protection goal is to reduce impact I over that period by 50% than the formula reads:

$$1/2 = I/GDP * 1,5 = 1/3 * 3/2$$

Eco-efficiency has to increase by a **factor 3**, that is, to produce one unit of GDP in 2040, only a third of resources/emissions is needed compared to 2020. This implies an annual increase of resource efficiency of more than 5%. Ambitious efficiency increases (like “factor 3” in two decades) could delink (decouple) economic growth and environmental impact.

Problem: So far, there is no empirical evidence that such efficiency increase rates are possible over many years. Most OECD countries show rates of 1–2% p.a. (see, e.g., Kurz 2014; Kurz 2019). Higher rates would require an “efficiency revolution” which has not materialized so far. Also government policy options to change this seem to be very limited. Moreover, if successful, stimulation of eco-innovation will stimulate growth and thus the intended reduction of impact I. This is called the “rebound effect” (see ► “Rebound Effects of Eco-efficiency”). More details on “factor 4” and “factor 5” are provided in Weizsäcker et al. (1997) and Weizsäcker et al. (2009).

Based on optimism about future eco-efficiency increases and on the neglect of rebound effects, the concept of “Green Growth” (see Kurz 2014) nourishes hope that the growth paradigm can survive. While critics point out to the lack of empirical evidence, defenders of growth refer to the chance of increases in the future. At least related to essential natural resources (like ozone layer, climate stability, ecosystem services), the survival of mankind depends on “save operating space” (Rockström et al. 2009). With technological over-optimism, planetary boundaries could be violated and processes triggered which are out of human control (tipping points). Without evidence for upcoming quantum leaps in eco-efficiency, economic growth is the variable which has to be controlled. Under given conditions, the only form of green growth is de-growth (in rich countries).

In sum: Given the empirical trend in efficiency increase, growth and sustainable development (e.g., climate protection) are incompatible. This holds not only related to climate protection goals (SDG 13) but also to material flows (material efficiency) and to biodiversity (efficiency of land use). As delinking by high rates of efficiency increase fails, ambitious environmental goals turn into restrictions for output (GDP growth). It is then necessary that a smaller scale of output contributes to reduce input (of environmental resources). In macroeconomic terms, this means a decline of GDP (de-growth); the microfundament is less consumption of private households (sufficiency, changes in lifestyle). Either (rich) nations give up their growth goals and growth policy or they will fail to comply with their SDGs and hence shift incalculable burdens on (grand-)children: either give up income or give up moral integrity. If the environmental sustainable development goals dominate, growth is no longer desirable.

A more general formula and an extension is the so-called **IPAT** equation:

$$I = I/GDP * GDP/person * persons$$

$$\text{Impact} = \text{Technology} * \text{Affluence} * \text{Population}$$

For the reduction of environmental impact I, three strategic options are available:

- **I/GDP**: reduction of the impact per unit of output (GDP), that is, **eco-efficiency**.
- **GDP/person**: reduction of income per person which is related to a reduction of consumption expenditure, that is, a fundamental change in lifestyle, that is, **sufficiency revolution** in the rich countries (see ► “Sufficiency”).
- **Persons**: Stabilization of (world) **population** contributes to lower I. Stabilization is a side-effect of increasing wealth (lower fertility rates). Additional instruments include birth control, financial incentives, education/empowering women. In some (rich) countries, decline is so fast that aging population becomes a serious (transition) problem.

Applied to climate change the formula reads:

$$\text{CO}_2 = \text{CO}_2/\text{kWh} * \text{kWh}/\text{GDP} * \text{GDP}/\text{person} \\ * \text{persons}$$

The goal of reducing CO₂-emissions could be compatible with economic growth, if carbon intensity of the energy system (CO₂/kWh) and/or energy efficiency of the economy (kWh/GDP) decline. One scenario for decarbonization within two decades could be: reduction of CO₂ per unit of GDP by 50% and switching to renewable sources for the “rest” 50%; a decline of population would allow for slight increases of GDP/person.

If GDP/person, that is, people’s income increase no more, would this be the end of increasing the “wealth of nations” which has been the explicit promise and job of economics since 1776? This dismal perspective is unavoidable if income is the only determinant of well-being/happiness. However, this is not the case: end of growth is not end of the pursuit of happiness. A further extension of IPAT illustrates this (with H for happiness):

$$\text{I} = \text{I}/\text{GDP} * \text{GDP}/\text{H} * \text{H}/\text{persons} \\ * \text{person (IPATH equation)}$$

The challenge is to generate happiness with less GDP, that is, less related to output of the economic system. For more details on IPATH and double delinking, see ► “[Sufficiency](#)”.

The two core strategic options for SD are efficiency and sufficiency (population policy neglected). The efficiency option faces serious limitations like rebound effects (see ► “[Rebound Effects of Eco-efficiency](#)”). Moreover, efficiency increases in one field (e.g., reducing CO₂/GDP for climate protection) are not only based on innovation (i.e., reduced energy intensity) but also on substitution, that is, shifting of problems to potentially less “harmful” fields (e.g., expansion of renewable energy). However, the negative side-effects of substitution are never zero (e.g., critical materials and land consumption). Government policy could stimulate and direct the innovation process with financial incentives and regulation

but cannot guarantee results. Innovation is always a search process and outcomes are uncertain. These weaknesses of the efficiency option support the case for the sufficiency option and for sufficiency policy, which is widely neglected so far. This option addresses the real core of SD, which is on limitations (Begrenzungs-krise), socio-economic development within planetary boundaries. On the micro-level, it addresses individual responsibility, lifestyles, and values (consumers’ addictions). On the macro-level, this translates into challenging the growth paradigm. The core policy recommendation based on the sufficiency option is: replace growth policy by sufficiency policy.

Only with a combination of sufficiency (reducing production and consumption, that is, GDP) and an efficiency revolution (reducing resource input and emission per unit of GDP), there is a high probability for sustainable development, for example, decarbonization within two decades.

New Paradigm: Sustainable Development Replaces Growth

The Brundtland definition could serve as the imperative of the postgrowth society. Development and change will continue to be a fundamental characteristic also in postgrowth-societies. However, development has to be reembedded into society (Polanyi 1944) and into eco-systems. If this is successful, development is called “sustainable development.” In the postgrowth era, “growth” is replaced by “sustainable development.” Therefore, the new paradigm and the new era could be named “sustainable development” – replacing one-dimensional economic growth. Problematic with this terminology is that the term “sustainability” has been (ab-)used since 1987 in so many ways that it will be hard to establish this as the terminus technicus for a new age. However, so far no generally accepted term for the new era has emerged.

Sustainable development is the step from an expansive, imperialistic robber economy (Wenar 2016) towards a civilized economy. It is not a complete change of the (capitalist) system, and it is reform rather than revolution. However, the reform must be fundamental – not really covered

by the worn-out term “reform.” Therefore, “transformation” and “great transformation” (WBGU 2011) have been introduced to the debate and might be a more adequate formulation.

The permanent challenge in the process of economic development, especially during rapid transformation processes, is to rebalance society and keep up justice and fairness. “More for everyone” is no longer available as dominating mechanism for conflict resolving. In a postgrowth society, the prospect of overall increasing incomes is eliminated. Better life cannot come from higher incomes and more goods. As “expansion” and “more for all” is no longer available as a conflict resolution mechanism, redistribution issues tend to become more significant, a shift from “expand” to “conserve,” from “more” to “more fair.” Protection of and support for vulnerable groups (e.g., low income, handicapped) can only come from the reduction of other groups’ income or wealth – not from an increasing “cake.” The new focus is to defend and preserve the “wealth of nations”.

For economics as a discipline, the challenge is a scientific revolution, a paradigm change (Kuhn 1962). Economic growth dominated research and economic policy recommendations for decades. In the postgrowth-era “growth” could be replaced by the more open concept of (economic) “development” – as outlined by Schumpeter (1911). Core idea is economic development as an open decentralized search process without growth orientation but emphasizing permanent, sometimes disruptive change and transition processes which could be cumulative and destructive or rather smooth (by design). Economic development will continue to be driven by competition and by innovation. However, both of these fundamental concepts will have to be revised in the reembedding process. However, development is not an absolutely free and open process. Environmental boundaries and limitations together with (old and new) social development goals (poverty reduction, decent work, etc.) make development “sustainable.” Focus of economic research will no longer be on drivers of GDP growth, but rather on how to resolve conflicts between sustainable development goals, how to improve performance

in more than one of them, on exploring synergies and on the transformation process.

Diagnosing the end of an era is not easy in the middle of the transition process. It is not absolutely clear whether the growth era is over already. However, there is no doubt that it

- (a) Will end – this has been emphasized already by Mill (1848) and Keynes (1930). “The idea of a stationary state is an integral part of the ‘economic imagination’ and the ‘obsession with growth . . . will very shortly, as reckoned by historic time, come to an end.’” (Boulding 1973, p. 89).
- (b) Must end – as it is not compatible with the survival of mankind (as illustrated here in the previous section).
- (c) Is in decline – as substantiated by the empirical tendency of the falling growth rates and the numerous warnings of mainstream economics on vanishing of growth dynamics.

In the end, the decline and end of the growth age and the beginning of a postgrowth era could be based on a combination of changing individual preferences and changing political priorities. Well-informed people in rich countries are interested in personal integrity and do not want to live on cost of future generations, hence are willing to change lifestyles (sufficiency, demand side) and voting behavior (rise of green parties, F4F movement). This is affecting the competitive spirit which is driving growth and it supports the implementation of new environmental restrictions as barriers to growth (factor input, supply side). Consequence: GDP growth rates will tend to decline and eventually turn negative. Therefore, the question “what next?” is relevant and has to be addressed in research and in political debate.

“Postgrowth” stands for the era after the growth paradigm and for a postgrowth society. The term is referring to the old paradigm “growth.” “Postgrowth” has much in common with “de-growth” (► “De-growth”). However, there is a different focus. “de-growth” debates tend to continue the (GDP) growth rate orientation: growth rate has to be negative instead of positive. “Postgrowth” stands for a scientific

revolution (replacing the economic growth paradigm) and for a great transformation in economy and society (postgrowth society). After the growth era and the growth paradigm – what comes next? This is the fundamental question for a new social contract, the shared common interest that holds societies together and it is the very practical question of how to measure status and progress of society (i.e., what will replace GDP).

The sustainable development paradigm is based on a vision about “the future we want” (e.g., specified in the UN SDGs). In the new era, the individual dream of striving for a good life does not have to be buried. However, there will significant modifications of basic elements like work, income, consumption, status. Transformation is not just a (mechanical) “switch” from one state to another but an evolutionary search and learning process with high uncertainty. It is important to understand to what extent it will be a disruptive, spontaneous process and to what extent it could be designed by efficiency and sufficiency policy.

Implications for Measurement: Asset Approach

Sustainable development and “the future we want” (UN 2012) cannot be reduced to a one-dimensional goal and indicator but has to be replaced by a broader concept. Neither does individual happiness (well-being) depend on income only nor can the “wealth of nations” (Smith 1776) be measured by GDP only. The 17 UN SDGs (with 169 subgoals and indicators) are a milestone in this direction. In this context, GDP is still a relevant indicator (SDG 8) – but not longer the most significant one.

A multidimensional phenomenon needs more than one indicator for measurement. Improvement of one indicator should not be interpreted as “progress” without reflecting the change of other indicators. This was one core failure in the growth era, the mismeasurement of wealth and progress (see Stiglitz et al. 2009). As a consequence of mismeasurement, (increasing) income flows have been interpreted and perceived as progress. In fact, a large part of it stems from consumption of

assets and the substance of the assets is declining. Assets have been neglected to a larger extent, basically because they are hard to measure and it is even more difficult to quantify them in monetary terms.

In the era of sustainable development, conservation of assets is the core idea. These assets include environment (eco-systems, nonrenewable materials), human capabilities and know-how, produced structures and machines, social institutions.

Formulated in economic terms the capital stock (assets) of an economy includes environmental capital N , human capital L , produced capital K , and social capital S . Technological progress (know-how) could be measured as a separate factor T or as incorporated in A and K . The sum of all assets is national wealth W :

$$W = L + K + N + S + T$$

To conserve the wealth of a nation, all of these assets have to be conserved. These assets might be considered as substitutes to some degree and the challenge (political goal) would then be to conserve the sum of assets (Hartwick Rule; Hartwick 1977). If, for example, N is declining, this could and has to be compensated, for example, by increasing K . However, there are limits to substitution which have to be defined in the political process (essential resources like climate stability).

The potential of these stocks are the input factors in the production process and the result of their combination is the output of goods and services, a flow which is measured by the GDP:

$$GDP = GDP(L, K, N, S, T)$$

For each of these factors, the challenge is to conserve the substance. This substance is declining in the production process as a consequence of physical deterioration and because of innovation (technical and economic obsolescence; Kurz 2015). This is measured in economic terms as depreciation. To conserve substance, depreciation has to be compensated by investment, for example, new machines. For each asset investment, ln has to be as large as depreciation $ln = D$.

If I_n is smaller than D , the substance of the asset is declining, that is, the wealth of a nation declines, wealth is consumed today. Future generations are less wealthy and their ability to produce income also declines.

In the simplest case (closed economy) investment is possible only if part of the production is not used for consumption C but for savings S :

$$I_n = D = S \text{ with } GDP = C + S$$

Savings have to be large enough to compensate depreciation of all assets. Only with savings larger than aggregate depreciations ($S > D$), the economy has net savings (“genuine saving”; Dasgupta 2007).

It is possible to consume GDP totally (in case of emergency, for example, war, famine). The consequence of such over-consumption is the decay of the production potential. Future incomes and consumption levels will be lower – and this might start a downward-spiral of decaying production potential and over-consumption. Therefore, the confusion of gross income and net income is a short-term temptation but has disastrous long-term consequences. With the GDP measurement method, the decline will eventually also become visible.

In the sustainable development paradigm, the asset approach is the adequate measurement method. It makes the mismeasurement of the conventional GDP approach visible. The neglect of assets (wealth) is the most fundamental mismeasurement. All other weaknesses of the GDP (SNA) concept are well-known and most could be corrected: household production not included, public sector only with cost of input factors, defensive cost increase rather than decrease GDP, distribution is not considered, etc.

Compared to the elaborated and well-established GDP calculation, the asset approach is suffering from methodological problems as well as the lack of empirical data. The most important methodological problem is the lack of a common denominator, a unit that would allow aggregation. Some parts are easy to calculate in monetary terms (e.g., machines, buildings), while others cannot be adequately monetarized (value of species and

social capital). Although there is no complete and consistent statistical system available to measure the state and development of assets, there is at least some empirical evidence on quantities and qualities:

- L: In many rich countries, population is declining and aging, that is, quantity of human capital declines. Investment in education systems is low compared with the devaluation of knowledge and skills (e.g., sophisticated diesel engineering obsolete). Investment is focusing on the top tiers (e.g., elite universities), inclusion is in decline.
- K: The modernization of capital stock is suffering from low private investment. In addition complementary public investment (schools, bridges, railway system, etc.) is not keeping up with depreciation. Transformation is adding to this “stranded assets” (e.g., coal-fired power plants). Overall, K is in decline in many (rich) countries.
- N: Empirical evidence on the loss of climate stability, biodiversity, and global commons (ocean acidification and plastic waste) as well as increasing local (air, water) damage is overwhelming. Attempts have been made to “translate” this in monetary units, for example, for climate change by the Stern Report (Stern 2006) and for biodiversity by the global TEEB project (The Economics of Ecosystems and Biodiversity, <http://www.teebweb.org/>). Extraction of nonrenewable resources has resulted in a “resource curse” rather than in an increase of the wealth of nations (Norwegian sovereign wealth fund as one exemption). No doubt: N is declining.
- S: Social cohesion, volunteering, trust in democracy (equal rights and opportunities), government institutions, and legal system (anticorruption) are in decline (Putnam 2000). Radicalization and separation rather than integration and common sense seem on the move in many societies.
- T: Increasing by R&D spending (and global diffusion). However, economic effectiveness seems to decline (Gordon 2016).

Of course, these are just a few spotlights which cannot replace more detailed investigations and research. And of course, there are significant differences between nations (Dasgupta 2007). Nevertheless, the overall picture is dismal. Essential resources are depleted and almost none of the assets seems to increase. Therefore, even the “flexible” Hartwick Rule seems to be violated. Most countries and probably the planet in total are in decline. The once so optimistic perspective that every next generation will be richer than the one before has faded away. The world is in a regressive rather than in a progressive state. So what happened to the idea of progress? As it turned out it is a self-deception: There has been and there still is progress for many (rich) people, but not on a global scale, that is, no overall increase of the wealth of nations. As mankind is receiving the bill for over-consumption, only a few manage to escape the burden. To make these conclusions more solid, much more research would be needed in this field.

Policies for a Postgrowth Society

As the sustainable (postgrowth) economy and society is in many aspects fundamentally different from the growth age, change and restructuring has been characterized as “great transformation.” It is not just about decline (and rise) of industries, that is, standard structural change, but moreover it is a cultural revolution, change of values, attitudes, and institutions. The goal is a prospering economy and society within environmental limitations no longer depending on economic growth (Wachstumsunabhängigkeit). Independence of growth (Raworth 2017: “growth agnostic,” “A-growth”) is not a characteristic of any actual economy. This redirection of the development process has not yet started. And there is little experience how this could best be supported by government policy. Although it is clear that government has to play an important role (WBGU 2011), unrealistic assumptions about public policy capabilities have to be avoided.

As outlined two components are essential:

1. Shared long-term vision of “future we want” and good life – beyond supply of more goods. This positive vision has to be developed and communicated continuously – not only by government but also by civil society organizations and by the science system. Without this component, the transformation process will lose acceptance.
2. Professional transformation planning which minimizes transformation costs and frustrations – for individuals, companies, and the economy in total. Changes in GDP (per capita income) are still relevant, however no longer dominating government policy. Economic fluctuations will continue, that is, years with positive growth rates might occur.

Long-Term Vision

Could a postgrowth society be attractive and win voters’ support? This depends first of all on problem awareness. Do (many) people understand that their lifestyle is damaging the planet and burdening future generations? Sufficiency and de-growth are then welcome as a “pain relief” and there is willingness to pay a price. After all, this price is no exorbitantly high for two reasons: For wealthy people higher income is not highly attractive (decreasing marginal utility; Easterlin 1995) and future costs of inactivity would be even higher (Stern 2006). As illustrated already by Mill (1848) and Keynes (1930) a stationary state could be part of a positive vision. However, the visions and images created by the powerful needs-stimulating advertising-industrial complex drive societies permanently in the opposite direction.

The basic transformation conflict which will be hard to moderate is about intragenerational justice. Under de-growth conditions, protection of vulnerable groups means more redistribution of incomes and wealth. To protect low-income households from decline of income, higher income groups will have to pay more taxes. How will the privileged react? Do the lucky ones in the lottery of life understand their responsibility

and are they willing to share (more) with the less privileged? The uncertainty about the outcome of the redistribution struggle and the fear of individual social decline is a huge barrier to transformation. Investment in social capital (inclusion, participation, dialogue, and conflict resolution mechanisms) is vital and has to start today. The better prepared it is, the less painful will the birth of a postgrowth society be (Jackson 2018).

Transformation Process – Slower by Design, not Disaster (Victor 2008)

In the transformation process to SD, pressure increases for all groups. Different qualifications and skills are needed, often with lower payment and status, sometimes at different locations (dislocation). Overall, uncertainty is increasing with only vague hope for a better future. Starting from a quite comfortable status quo, defense of this status and aversion against change is plausible. During the transformation process, all forms of resistance will occur (in companies, in the political arena). Transition design and management will be crucial based on resilient and reliable institutions (schools, education, science, media, courts, police).

Government policy and the science system are confronted with unresolved research issues: To what extent is it possible to control and to manage macroeconomic growth rates? Is growth feasible (design vs. systems dynamics)? Now the issue not just about the slope of a trend curve but much more fundamental: How to end an era of almost hundred years of economic growth orientation (soft landing)? How to sustain microdynamics (creativity and innovation) and make sure that “stationary state” is different from “stagnation”? How to avoid a self-feeding crisis (socio-economic tipping point) with huge losses for all (like world economic crisis 1929).

First of all a reliable framework has to be established by definition of goals to reduce uncertainty and to change expectations: deadline for nuclear power, for coal-fired power plants, for fossil-fuel cars. Next, transition planning has to include stimuli and compensation measures to

make structural change more acceptable for affected people and companies.

All forms of growth policy have to be stopped: growth-stimulating measures (e.g., in the tax code), unspecific subsidies for R&D, revise deregulation. Laws which define growth as goal for government policy have to be abated. Government expenditure has to be restructured, for example, infrastructure investment: no new roads, runways and terminals – bike lanes and public transportation instead. Environmental restrictions have to be “translated” in regulations and concrete caps, for example, parking lots, runway slots.

What could government do to better prepare companies and managers for the no-growth world? Stimulate more competition or encourage more co-operation? Are higher (net) profits necessary to kindle (eco-, social-) entrepreneurial spirits? How to provide more (green) venture capital for start-ups? Companies are used to a growth world and are, in general, not prepared to thrive in a no-growth environment – where competition intensity might increase, traditional business models will fail and average entrepreneurial talent might not be enough.

Consumption and Product Innovation

The micro-fundament of postgrowth is consumption. Increasing incomes are needed to fulfill consumption wishes far beyond basic needs. Human needs seem to be unlimited and the business sector is not only producing new goods but also the preferences and the demand. Permanent product innovation keeps up consumers demand. Innovation is at the same time the engine of premature obsolescence. Acceleration of innovation is identical with reduction of product life-cycles. Hyperconsumption creates rising material and waste flows. All this is supported and stimulated by a sophisticated market research, marketing and advertising industry. However, this industry is just the appendix. The real cause is misled innovation. The flood of “new” consumer goods has to be critically evaluated and redirected so that it can really contribute to good life instead of driving the rat race. The core question of sustainable

development in rich countries is “how much is enough” (sufficiency). This starts a creative search for new lifestyles and consumption patterns which emphasize “less” in all fields of consumption (from mobility to housing and food). This is not the end of the pursuit of happiness and increasing well-being. However, fundamental learning and change process (social innovation) are necessary. How could government support and stimulate this by systematic sufficiency policies? Many measures have been proposed (e.g., general speed limit, restrictions on advertising, control of premature obsolescence) but there is still a lack of consistent and effective concepts (Potocnik et al. 2018).

Future of Work and Sufficiency Policies

Consumption is part of the decision on time allocation: how much time for work (income), how much for leisure time (work-life-balance)? In a broader perspective, work is not just paid work but includes all activities which are necessary to create the social product and to sustain individual and social assets (capital). Markets and market incomes reflect only part of it. Work in private households and in civil society organizations is neglected, that is, investment in human capital and in social capital. Work is not just a sophisticated trick to organize a peaceful and pious society (as Smith 1776 suggested) but a component of a good life which is not just important for income generation but also self-esteem and for social inclusion (Illich 1973; Schumacher 1973). Flexibility and reduction of working hours will be key as well as the organization and enrichment of work. These are important elements of “good life” in a postgrowth society. Government, companies, and unions have to reconsider their concepts to support more flexibility and less focus and paid work.

Income and Redistribution

Fairness is an important component of happiness and it is a core issue of good life in postgrowth societies. Without growth distribution becomes more important. This includes equal opportunities (starting in the education system), access to public goods (infrastructure), distribution of income and wealth. All government activities will have to

include distributional aspects more systematically. In transformation processes, fear of social degradation (“Abstiegsangst”) is increasing and has to be addressed. After a period of “greed is good,” it is important to emphasize the fundamentals of the social contract: There have to be (equal) chances for everyone (social mobility). And those who make it to the top have an obligation to repay to society (for what they have received from the beginning in the health care and education systems to the institutions which guarantee their safety). Success is never the result of individual effort only.

Perspectives

While the global debate on sustainable development and on the UN SDGs has broad public and political attention, this is almost never framed as a “postgrowth” debate. In the context of poor countries, this is not surprising. But in advanced rich countries, the perspective of long-term growth has to be addressed instead of systematically neglecting it. It should be addressed more intensively in (economic) research and in public policy for two reasons:

1. There is a realistic chance that long-term zero or negative growth will dominate in many high developed countries. There are many (system-immanent) drivers in this direction which in combination might be strong enough to be beyond control (optimal adaptation).
2. The values and policy priorities have changed significantly as a consequence of the knowledge about (the cost of) climate change and biodiversity loss. With new priorities conflicting goals have to be reevaluated. If growth is incompatible with environmental sustainability goals, it turns from problem-solver to problem. It is therefore no longer desirable and no-growth is not a disaster. Government policy has to switch from supporting to restricting growth.

For both reasons, it is urgent to reinforce research and public debate on the long-term

visions which could replace the growth promise and on the transformation period which could be crisis-ridden. The window for debate is closing and pressure to act is increasing. Only few pioneer countries are moving ahead (such as Denmark and Sweden, see Sachs et al. 2019), although there is room to move even under conditions of international competition. Environmental disasters are hitting everywhere; change of awareness, attitudes, and behavior is proceeding simultaneously in many countries. The typical prisoner's dilemma (co-operate only if the others would do so) is no longer relevant. And yet political change is so slow.

As it is obvious, well-reported, measured, and documented what happens to the present generation and what will hit future generations even more dramatically, it is strange to see all kinds of debates on additional public debt to finance investment, for example, in (sustainable) infrastructure projects in the context of a "Green New Deal". This could reduce next generation's environmental cost (e.g., cost of climate adaptation) and hence leave them with higher net income. Instead they will have to pay higher taxes to repay the government loans. So the net income effect may not be much difference, however, the risk portfolio is much more positive: It is easier to handle creditors than to handle the incalculable risks of the climate system. However, this debate misses the core point: This generation should not continue to burden future generations at all – neither with climate change nor with additional government debt. Instead it is high time to start with repaying the debt of decades of over-consumption. This is not a time of emergency – at least not in the rich nations. Means, tools, and technologies are available. Therefore, there are no good reasons for passing on the burden only to continue the over-consumption party. The Corona Crisis has interrupted the party, but hopes and expectations are that a fast recovery and the return to normal is possible (V scenario). People and nations are not prepared for a "new normal" yet.

As outlined already by Veblen (1899), (demonstrative, conspicuous) consumption is the fundament of social status. Status and recognition in a

postgrowth society have to be delinked from consumption, income, and wealth. This reduces the incentive to go for and to defend higher incomes. Other components need to get more public attention and recognition, for example, intellectual contributions and volunteering in social services. As emphasized by Schumpeter (1942), capitalism cannot survive if it is not attractive for its intellectual elites to defend the system.

Science system is free (not) to address the postgrowth issues. As policy priorities change and public interest increases (e.g., S4F), responsible science has to respond, or its relevance will decline. There is the perception that "panic" (Greta Thunberg) would be an adequate reaction to the sustainability (climate) challenges. In panic human beings and society could do all kinds of irrational things. If science does not provide answers and guidance, unexpected panic reactions might dominate. "Listen to science" is good advice only if science delivers – not just diagnosis (of climate change) but also solutions. The end of the growth age hits rich societies and citizens unprepared. Most people are still in the delirium of the growth party – as the band continues to play on the Titanic.

Social justice

Definition

Power is a complex and contested concept that is notoriously difficult to define. It relates to the ability to influence people or a situation. This ability to influence can involve a continuum of varying degrees of pressure to obtain compliance or agreement, from persuasion through force – either threatened, physical, or legal (Lukes 1974). Power can be exercised directly in interpersonal interactions and indirectly through extra local relations of ruling of the power elites.

In the context of sustainable development, power dynamics are at the center of struggles over the rights and interests of businesses, governments, groups, communities, and ecosystems. There is no straightforward fit between these stakeholder's often incompatible rights and interests. In fact there are differing levels of status, resources, and political leverage which skew sustainability issues in favor of dominant interests. Sustainable management needs to address the issue of inequality between the range of stakeholders involved in ecological and social license conflicts. If the status quo of power inequalities persists, it will continue to be difficult to achieve change toward pro-sustainability outcomes. In the absence of power-equalizing mechanisms, it will be hard to address the lack of accountability for failures of social and

environmental responsibility of business operations and governments. Consequently, to enable sustainable development, there is a pressing need for leadership which is based on cooperative and nonexploitative use of power and power-equalizing strategies.

Introduction

There is a worldwide struggle occurring between the rights and interests of nation-states, multinational mining companies (MNCs), citizens, and ecosystems. How the trade-offs occur indicates the flow of power with high-power entities (e.g., MNCs) tending to gain at the expense of low-power groups (e.g., small rural communities and animals in proximity to mine sites). Dominant interest groups in society have established systems of governance and norms for business practices that are maintained to their advantage through legislation, policies, the media, and dominant discourses. Marx and Engels (1848) historic claim that the owners of the means of production are the elites of society remains true in contemporary forms of capitalism which is based on often unchecked globalized flows of capital and labor.

Foucault (1980) explains that dominant ideas of the powerful can create docile bodies of the citizenry. The citizenry capitulates, in this case, to the logic of capital in the hands of the elites and their right to plunder the earth's resources for the supposed benefit of society. MNCs gain power and authority through legislation (e.g., mines acts that approve licenses and leases); political influence; leverage through the promise of jobs, including the threat to cut jobs; the promise of taxes and royalties; and access to human and financial resources. MNCs can also leverage social influence by gaining a community license to operate. The government has power and authority by virtue of its regulatory role of business; the legally constituted system of governance; its representative role on behalf of the public's interest; and access to human and financial resources.

Foucault (1980) explains that where there is power, there is also resistance to that power. This relates to the idea of power not being a possession or given to the elites but able to be exercised and challenged through a range of social processes and institutions. Resistance and reaction to the business practices of MNCs typically take the form of activism by impacted stakeholders and their supporters. Impacted social groups and communities have power that is located in democratic processes such as social power to resist via the right to protest and lobby; legal redress such as class action against business entities for harm and loss; submissions against licensing and appeals to business operations; voting; and the ability to collectivize to make claims to protect human rights, health, and the environment. People power can take many forms and has varying degrees of ability to influence high-power stakeholders. At the same time, people power does not always have direct legal authority or the ability to readily access capital and other resources to mount campaigns and raise public awareness in situations of ecological conflict.

When environmental and social justice interest groups such as Get Up! garner financial and political influence, their authority is relentlessly challenged by the dominant vested interests. Get Up! is a community-based and community-funded organization with a website that promotes activism for a fair, flourishing, and just Australia (see <https://www.getup.org.au>). The maligning of leftist and greenie groups such as Get Up! reached a fever pitch in 2014 when the prime minister of Australia cultivated an “us versus them” politics. He denied climate change was an issue and argued against a carbon emission tax on polluting industries, calling on people to join his “Team Australia” or be constructed as anti-development and anti-Australian. In such conservative, neo-liberalist contexts, MNCs can exacerbate patterns of advantage and disadvantage in a host society. For example, in early 2019, a backlash from powerful industry groups against the Western Australian state government saw the government dropped its attempt to legislate environmental offset requirements on industry.

The chairman of the government’s Environmental Protection Authority was targeted in a multi-million dollar smear campaign that resulted in the government withdrawing its environmental offset legislation.

A dominant discourse that maintains the power of big business is that they are crucial for nation-state’s economic survival. This is linked to an unquestioned belief that wealth so generated will trickle down to bring about equality of opportunity and address the welfare needs of the society. The key assumption is that capitalism and the wealth-centralizing tendencies of MNCs can provide for human well-being and environmental sustainability. This assumption is being challenged on a number of fronts by the anti-globalization movement and other activist groups and organizations. Nevertheless, the dominant mode of production continues to be the use of natural resources, and often the exploitation of human labor and animals, for the extreme wealth of a few entities and individuals. Mills (1957/1978) claims the very rich are the power elite which includes the military, the state, and corporations. He writes that the power elites of society have a myriad of ways to accumulate advantages that generate further wealth. This accumulation of extreme wealth is possible due to the exploitation and profiteering of elites at the expense of disadvantaged groups, localities, environments, and animals. That is, the profit-driven logic of big business, especially in the mining sector, creates inequality and can exacerbate pre-existing inequalities in the host nation-state.

Inequality is embedded in western capitalist societies which have adopted strong neoliberalist policies and a light touch approach to regulating the mining and large-scale farming sectors. Neo-liberal ideology favors tax breaks and concessions to big business to stimulate the economy. It is usually coupled with a constrained or regressive welfare, education, and health policy agenda which does little to address the unfair access to the wealth of a society. In Australia, for example, there is a two-tiered economy where the wealth accrues to the owners of big business entities. The other economy for the majority of the population is typified by poverty, housing insecurity,

unemployment, stagnating wages, impoverished rural localities, and health disparities. Globally, the gap between the rich and the poor is widening unless governments are proactive in implementing universal welfare and income protection and in equalizing taxation disparities.

The basis for economic and land rights inequality is located in the legalized pursuit of profits by privately owned MNCs whose business is premised on the depleting of the natural resources. For example, the ability of Indigenous People to claim exclusive ownership to their ancestral lands remains contested even in countries where the legal recognition of their land rights has been achieved. When MNC power is not sufficiently checked, it results in the plundering of nation-state's and sovereign people's lands and resources.

The Sustainability Issue

Globally, there are increasing ecological conflicts; gaps between wealthy and poor people and countries; loss of biodiversity; and climate change impacts. These factors can combine to disproportionately harm disadvantaged groups and countries and add to environmental degradation. There is little evidence that claims of corporate social and environmental responsibility by MNCs are of sufficient substance to be turning these concerning trends around. Corporate social responsibility (CSR) refers to business's proactive efforts to ensure a social value to their operations. Ideally, CSR would manifest when social, environmental, and economic dimensions of sustainability are in balance. A dynamic balance between social, environmental, and economic sustainability is not possible in the case of the extractive industry sector. Mining is inherently unsustainable. Profits are possible precisely because of the exploitation of the environment and unequal treatment of stakeholders. It is usually the responsibility of nation-state governments to ensure that industry is adequately regulated. Some writers suggest the failure to ensure the sustainability of industry is an example of state crime.

CSR tends to be limited to social reporting of a narrow range of philanthropic activities, and a commitment to CSR rarely extends to directly informing the governance and operation of the business entities. The idea of the triple bottom line challenges business practices to be geared toward economic, environmental, and socially sustainable outcomes. Yet as has been shown, there is an unequal set of power dynamics where economic interests outweigh environmental and social sustainability claims. CSR is often espoused but not evident in the resource extraction sector which has the greatest adverse impact on people, place, and ecosystems. MNCs should not be the sole arbiters of business sustainability and CSR to enable this sustainability when they are collectively the main threat to it.

A different order of ideas and strategies is needed to counter the limits of industry-defined and industry-instigated CSR. Issues of unsustainable development are most evident in situations of conflict over land rights, the rights of communities to live without being polluted or intruded upon by MNCs, and the rights of animals and ecosystems to survive. These also tend to be situations of major power disparities skewed in the favor of MNCs where the trade-offs are determined by business interests. When there is such unequal bargaining power, attention needs to be given to how power is being used and possibly abused. CSR literature tends not to explicitly confront this issue of unequal power as the issue that needs addressing for sustainable development.

The idea of *critical* social responsibility draws attention to the unequal and unfair access to power of MNCs especially in the mining sector and often in tandem with governments. Governments can experience conflicting loyalties as they are meant to be both the regulator of that industry and act in the interests of the public. Critical social responsibility refers to strategies which constrain the power of dominant stakeholders and seek their accountability to low-power stakeholders (Ross 2017). When the environment is the impacted stakeholder, it becomes more pressing to ensure it is not irreversibly harmed. For example, despite rigorous research by an expert, an Australian state

government refused to accept that the increasing acidity caused by large-scale mining in the remote Burrup Peninsula is causing the deterioration of Indigenous rock art. The evidence is not enough to shift the dominant interests of government to protect the largest and oldest collection of rock art in the world. This presumably would look different if the rock art was not located in a booming resource area. The government and industry groups argue that development and the rock art can coexist together, maintaining their dominant discourse of being the authorities and experts on the matter. The art is being dissolved by the acid from mining operations, and the science that proves this is a known risk worldwide. Yet more mines and expansions are in the development pipeline at this time.

Interrelatedly, in situations where local communities are being adversely impacted by mining operations, it is manifestly unfair that these same communities have to struggle to be heard about those impacts (see, e.g., a community activist website CAPS Inc., <https://caps6218.org.au>). Research shows that industry intrusions into communities have very divisive effects; it depletes infrastructure and social capital, with no obligation on the business to compensate for harm done. Sustainable development is not possible in circumstances of unequal power between the stakeholders. The piecemeal successes that are hard-won by environmental activists are not of sufficient magnitude to turn the tide of plundering of the planet's shrinking resources.

Ways to Enable Power Equalizing for Sustainable Development

There needs to be a range of power-equalizing strategies across all the points of leverage used by MNCs to maintain their control. The main purpose of big business is profit-making for their shareholders and owners. The logic of profit-making is not sustainability centered or driven. It cannot be left to the voluntary self-regulation of businesses to care about, or to know, what the public's interest is and to act in the public's interest. Nation-states that hold the regulatory

authority to ensure development is sustainable will always be under pressure from big business and in tension with impacted stakeholder's rights and interests. Thus, it is essential that legislation in the areas of environmental protection; health and public safety; foreign ownership of land; and planning is attuned to challenges from business interests. As part of the lobbying and pressure tactics of big business, nation-states could limit the use of media campaigns by business as one point of counter-leverage to self-interested promotion. Where state-level authorities are overridden by business pushback against pro-sustainability measures and decisions, the federal level of authority needs to be invoked. When the governance system of a nation-state is overridden by MNCs and when failures of CSR occur, an international authority with legally binding powers needs to arbitrate on the sustainability issue. The social precautionary principle should be exercised in tandem with the environmental precautionary principle at this international level. Higgins (2010) argues that there should be no business or entity which is beyond the rule of law. She proposes a Bill of Nature's Rights and an extension of the Declaration of Human Rights to include Mother Earth. Brown calls for a global democracy, an international parliament of the people:

We need a strategy. We need action based on the reality that is our own responsibility [as citizens of Earth], everyone's responsibility ... democracy – ensuring that everyone is involved in deciding Earth's future – is key to success. (2014, p. 194)

In specific situations of ecological conflict, direct strategies which engage all interested stakeholders need to be premised on dialogue where parties meet as equals and where power is equalized and nonexploitative. The dialogues need to be pro-sustainability focused with the requirement that the economic dimensions of the sustainability issue need to be in balance with social and environmental considerations. The multi-stakeholder dialogues need to be backed up by a legal requirement of participation by high-power stakeholders to ensure appropriate accountability for harm done and to negotiate fair and sustainable outcomes.

One method for ensuring a power-equalizing approach to the dialogues is the use of legally binding warrants or agreement protocols. The warrants that will need to be instigated and upheld by all parties are:

1. A willingness to focus on matters of significance to impacted stakeholders
2. Attention to, and the checking of adverse effects of, corporate and government power relations
3. Substantive and relevant contributions to the issue
4. Building sincere relationships and holding relationships over the life of the issue (Ross 2017, p. 9)

The warrant-based dialogue method is designed to enable equal participation of all interested stakeholders. There is not though an equal responsibility to resolve the sustainability issue. The high-power entities have different orders of responsibility, that is, higher levels of responsibility, to take accountability for their actions, or failures to act, that have caused the unjust or unsustainable situation. It is not the environment in all its diversity and dynamic livingness that is responsible for human intrusion against it. It is also not the communities who are experiencing, for example, industry-generated pollution or devastation from the collapse of tailings dams that are responsible for the harm.

Summary

Sustainability managers have a role to play in providing leadership in situations of ecological conflict to ensure power-equalizing strategies are employed as part of MNC's corporate social responsibility. MNCs can become sustainability focused by supporting power-equalizing strategies with adversely impacted stakeholders. Further, MNCs' willingness to fairly negotiate the trade-offs between economic, social, and environmental aspects of development can significantly contribute to the securing and keeping a community license to operate.

Prahalad's "Bottom of the Pyramid"

Maria Roszkowska-Menkes

Department of Management Theory, Warsaw

School of Economics, Warsaw, Poland

Synonyms

Base of the Pyramid; BOP; Inclusive Business

Definition

Bottom of the Pyramid (BOP) (also referred to as "Base of the Pyramid") is a term used to describe the poorest socioeconomic segment of the world's population, as well as a management concept that recognizes this segment as a viable market for the world's largest companies. The concept was introduced in the seminal article by Prahalad and Hart in 2002 and subsequently expanded upon in Prahalad's book *The Fortune at the Bottom of the Pyramid. Eradicating Poverty through Profits*, published in 2004.

Prahalad (2004) describes four consumer tiers that constitute the **world economic pyramid**. The very top of it is composed of middle and upper class in developed countries and the few rich from the developing world. They comprise around 20% of the global population and account for about 85% of total income. The middle of the pyramid, tiers 2 and 3, encompasses the middle-income people in developing countries and the poor in developed markets. Finally, the 4 billion people (two-thirds of humanity) largely excluded from the global economy represent the bottom of the pyramid. As defined by the author, this is the world's population with annual income, based on purchasing power parity (PPP) in US dollars, less than \$1,500. It represents a \$13 trillion market full of unsatisfied needs and a perfect testing field for new products and technologies for consumers all over the world. Prahalad proposes that multinational corporations (MNCs) can seek new growth opportunities in low-income markets

and, at the same time, contribute to poverty alleviation and the creation of **inclusive capitalism**. However, doing business at the BOP poses great challenges for companies and requires radical innovation in technology and business models.

Characteristics of BOP Markets

The growing income gap between tier 1 and tier 4 consumers hinders the latter's access to the global economy. Despite its size, the BOP for long has been neglected by the corporate sector, since low-income markets with hard-to-reach and culturally distant consumers have been perceived as not viable (Prahalad and Hart 2002). However, as Prahalad (2004) argues, the view of consumers in developing countries among managers in MNCs has been shaped by a set of false or outdated assumptions. First, it has been assumed that BOP consumers cannot afford even basic Western products and services and, thus, MNCs with the current cost structures cannot profitably serve that market. The second common assumption is that the poor have no use for Western products and services. Third is the view that BOP consumers do not need advanced technology and are not willing to pay for it, and thus, the BOP cannot be a source of innovation. Fourth, BOP markets have been perceived as not important to the long-term growth and success of MNCs. Fifth, initiatives in BOP markets have been viewed as not challenging enough to attract managers willing to run them.

However, the author (Prahalad and Hart 2002; Prahalad 2004) shows that due to ever increasing competition in saturated tier 1, 2, and 3 markets, companies looking for untapped possibilities to grow have started to challenge the dominant views of the poor. The aggregate buying power of the poor is large enough to offer substantial growth opportunities. Tier 4 consumers, contrary to the common view, are very brand conscious. The poor often buy branded and luxury items as an illustration of their aspiration to a different quality of life. They also spend a significant percent of their income on connectivity, as it contributes to the improvement of their economic

opportunities. They are also eager to try out new technologies “because they have nothing to forget” (Prahalad 2004, p. 16). Consumers at the BOP are value-conscious, expecting great quality at prices they can afford. Since many BOP consumers live in high-cost ecosystems controlled by local monopolies and slumlords, they usually pay much higher prices (the “poverty penalty”) for products than middle-class consumers. This creates opportunities for large corporations, whose economies of scale and efficient supply chains allow them to deliver higher quality goods at lower prices without sacrificing attractive margins. Although many tier 4 consumers live in hard-to-reach rural areas, there is also a huge urban population. Additionally, with new information and communications technology, efficient distribution systems can be created even in rural communities.

Key Assumptions of Prahalad's BOP Concept

Prahalad's concept is based on four basic assumptions. First, engagement of private enterprises at the BOP is a critical driver of inclusive capitalism (Prahalad 2004). It creates access to high-quality products and services, previously reserved for the middle-class, and reach. Giving the BOP consumers choice creates a way to escape the high-cost ecosystems in which most of them live.

“By stimulating commerce and development at the bottom of the economic pyramid, MNCs could radically improve the lives of billions of people and help bring into being a more stable, less dangerous world” (Prahalad and Hammond 2002).

Second, the BOP provides new business opportunities that can be realized only through innovation (Prahalad 2011). **Innovation at the BOP** is a continuous process of learning and refinement. According to the author, the innovation process needs to start with deep immersion into local communities in order to access information about their unique needs and problems. While BOP markets are heterogeneous, solutions must be specific to an industry and to a particular target

within the BOP. Companies need to focus on: (1) Affordability – providing world-class-quality solutions for low prices; (2) Awareness – ensuring that the consumers know what is available and how to use it; (3) access – ensuring that products can be accessed even in the most remote locations; (4) availability – ensuring an uninterrupted supply of products and services.

Third, initiatives in BOP markets must be integrated with the firms' core businesses (Prahalad 2004). The author believes that given the size of the BOP markets and opportunities they offer, MNCs do not need to engage in charitable initiatives to help the poor, but rather act in their own best self-interest. The approach presented by Prahalad is based on a win-win assumption – BOP initiatives can contribute to both enhancing the quality of life of local communities and improving companies' profitability. He argues that a shift in thinking about the poor as a problem toward recognizing them as consumers and entrepreneurs opens up new business opportunities. Additionally, MNCs can leverage their experience from serving low-income markets and transfer sustainable innovations for the BOP to their traditional, high-income markets (Prahalad 2011).

Fourth, solutions to the problem of poverty need to be co-created in an ecosystem (Prahalad 2004). Alleviating poverty requires wide intra-sector and intra-industry partnerships. Business opportunities at the BOP cannot be realized unless there is cooperation between large and small companies, governments, nongovernmental organizations (NGOs), development agencies, as well as BOP consumers and entrepreneurs. Eradicating poverty requires large-scale entrepreneurship. However, according to the author, it is MNCs that should take a leading role in this process. Developing necessary infrastructure at the BOP is a resource- and management-intensive task. Large corporations have managerial, technological, and financial resources to handle such initiatives. They also have access to unique global knowledge base and can transfer solutions from market to market. What is more, by sharing their knowledge and capabilities, MNCs are in the best position to bridge various stakeholders and stimulate cooperation.

Operationalization of the BOP Concept

Commercial Infrastructure at the BOP

To overcome the challenges of doing business in low-income markets and serve BOP consumers, companies need to develop the right commercial infrastructure (Prahalad and Hart 2002). The popular assumption is that the poor cannot afford standard Western products and services. Many people at the BOP are either unemployed or are paid below the living wage. Thus, creating buying power is the first condition enabling business operations in low-income markets. This can be achieved through initiatives focused on increasing access to credit and earning opportunities for the local communities. While commercial credit is key for development of market economy, historically it has been unavailable to the poor since most of them operate in the informal economy. Extending credit to the poor and supporting micro-entrepreneurship is possible through a microlending model.

Further, the vast majority of tier 4 consumers live in poorly connected rural areas and urban slums. Thus, investment in better distribution systems and transport links is essential to serve these hard-to-reach communities and improve their access to high-quality products and services.

Another crucial element of commercial infrastructure at the BOP relates to shaping the aspirations of local communities. This can be achieved through investment in sustainable development and consumer education. Such investment not only positively influences consumer choices at the BOP but also may provide the early market pull for disruptive, sustainable technologies in developed markets.

Finally, serving tier 4 consumers is not possible without tailoring solutions to the unique needs and problems of local markets. New business models should not disrupt local cultures and lifestyles. MNCs must combine advanced technology with deep local insight. For example, selling products in small packages so that the poor can afford it, but at the same time investing in sustainable packaging materials in order to decrease the environmental impact of the additional waste produced by the local consumption.

Success Factors

According to Prahalad and Hart (2002), business success at the BOP depends on several factors. First, MNCs need business leadership with high cultural sensitivity and deep understanding of local complexities. Second, MNCs must invest in R&D and market research focused on the unique needs of the poor and possible adaptations of foreign solutions that could address them, as well as identification of potential applications of local solutions. Third, success at the BOP requires the creation of business models that increase employment intensity and, as a result, boost income among the poor. Further, MNCs must reinvent their cost structures to offer affordable products and services. Business processes need to be focused rather on functionality and not the product itself.

Finally, since empowering the lowest income classes generates threat to the existing power structures, serving tier 4 consumers requires building a local base of political support, as well as the creation of alliances with different stakeholders, including local governments, SMEs, and NGOs. With wide partnerships, corporations not only gain deep local insight into and access to resources but also build their credibility.

In an article co-authored with Brugmann (2007), Prahalad puts special attention on MNCs' ability to build trust-based and partner-like relationships with NGOs involved in helping the poor. The interests and capabilities of corporations and NGOs increasingly converge, encouraging the co-creation of "integrated business models in which the company becomes a key part of the NGO's capacity to deliver value and vice versa" (Brugmann and Prahalad 2007, p. 16). Cooperation between NGOs and the private sector aimed at developing hybrid business models in low-income markets helps deliver products at low prices to BOP consumers and/or provide niche products to consumers in developed markets. It increases the corporation's credibility and builds its legitimacy, while expanding the NGO's impact.

According to the authors, governance of company-NGO partnerships should be based on

the following principles (Brugmann and Prahalad 2007):

- Engagement of local customers and entrepreneurs
- Task-oriented relationships
- Combination of global knowledge and standards with local insight
- Companies and NGOs as equal partners
- Social legitimacy through creation of value propositions with credible economic, social, and environmental dimensions

Criticism

Despite being a very appealing proposition, Prahalad's concept has attracted a range of criticism. Karnani (2007) argues that "there is no fortune to be made by selling to the poor" (p. 97) for at least five reasons. First, the author points to the size of the markets presented by Prahalad as having been largely overestimated. According to the World Bank, estimates are of 2.7 billion, not 4 billion people living in poverty in 2001 and, since the average consumption of poor people is \$1.25 per day, this implies a BOP market size of merely \$1.2 trillion. Additionally, BOP consumers spend 80% of their income on basic needs and not on luxury items. Second, providing products in small packages and creating access to credit do not make the products affordable. On the contrary, price per unit is higher than if the product is bought in large packaging and paid for in cash. Third, it is not MNCs that should take the lead in alleviating poverty, but rather local SMEs, which are better suited to exploit opportunities at the BOP. Low-income markets are geographically dispersed, poorly communicated, and culturally diverse. Products targeted at the poor are not technologically complex nor brand intensive. This all reduces the economies of scale in distribution, technology, operations, and marketing, making these market not attractive for large corporations. Karnani (2007, 2009) argues that the BOP concept is "dangerous delusion" (2007, p. 96) because it creates room for exploitation of the poor, who are not value-conscious consumers,

but rather often make economically irrational choices. "The only way to help the poor and alleviate poverty is to raise the real income of the poor" (2007, p. 100) and this can be best achieved not by selling to the poor (even at lower prices) but by buying from them, i.e., looking at them as producers. The key is to create opportunities for steady employment at living wages, increase productivity, and develop efficient markets. Finally, the author concludes that Prahalad's propositions detract from the failure of governments in fulfilling their traditional functions.

Similarly, Jaiswal (2008) argues that the engagement of corporations in economic development of **least developed countries (LDCs)** is unrealistic because of extreme poverty, poor legal framework, high level of corruption, as well as the underdeveloped infrastructure and financial system. He points out that the cases of large corporations thriving at the BOP presented in the literature refer to the most emerging markets, such as India, Brazil, or Mexico, and not LDCs in general. What is more, Jaiswal argues that MNCs should not take a leading role in helping the poor, as their activities are not only typically ineffective, but even detrimental. Marketing practices of MNCs at the BOP can negatively affect the quality of life of the poor by encouraging them to allocate scarce resources to non-essential consumer products instead of satisfying basic needs, such as nutrition and health (see also Gupta 2013). The author underlines that the key to poverty alleviation is free basic education and affordable technical education delivered in cooperation between private and public stakeholders.

Simanis et al. (2008) criticize the propositions presented by Prahalad for oversimplicity and translating poverty alleviation to the "managerially accepted language of customer needs and product development" (p. 57). According to the authors, this strongly economic approach increased opposition among the non-profit and public-sector actors, many of whom started to perceive the BOP merely as a smart business strategy for selling to the poor. Additionally, the BOP has been reduced to one homogenous market, while "in fact, it is not a market at all (...)

[but] a demographic classification” (p. 58, addition – M.R.). The markets at the BOP first need to be created and this requires a co-venturing approach based on empowerment and the participation of local communities (see section BOP 2.0 and the BOP Protocol in ► [Base of the Pyramid](#)).

Synonyms

“Vorsorgeprinzip”

Definition

The Precautionary Principle is an environmental policy principle used in legislation, policy, and risk management. New technologies like climate engineering, genetically modified crops, nanotechnology, or artificial intelligence are often linked to risks, which are difficult to predict. The Precautionary Principle is applied in decision-making about uncertain but plausible threats to human health or the environment, e.g., as a consequence of using new technologies. In situations which lack scientific certainty, it can be challenging to find the right measures to protect human health or the environment from harm. Put simply, the Precautionary Principle states that lack of certainty shall not be a reason to refrain from taking action to tackle a threat. In other words, it says that in a situation of uncertainty, regulatory action might be a good option (even if scientific data are incomplete or controversial). The Precautionary Principle should be applied if possible effects on human health and environment are serious or unacceptable, even if the risk cannot be estimated. In such situations of uncertainty of scientific results, the Precautionary Principle can be followed as a guidance in decision-making, in the preparation of new legislation, and in applying existing regulations. The Precautionary Principle applies where the probability of occurrence and or the extent of effect cannot be described sufficiently due to incomplete data, inconclusiveness, or public debate about risks. There are various forms of the Precautionary Principle differing

Praxis

► [Phronesis](#)

in strength and weight regarding the need to take action and/or to provide data about the expected outcome. Generally the Precautionary Principle can be summarized as follows: as “uncertainty not being a reason for non-intervention” or as “uncertainty being a reason for (or even demanding) action.” Other policy principles related to the Precautionary Principle are the preventive principle (taking measures to avoid harm), the risk-based principle (scientific evidence-based decision-making), the source principle (treating environmental damage at the source if possible), or the polluter pays principle (actor responsible for the environmental damage carries the cost).

Introduction

The Precautionary Principle is an environmental policy principle intended as a guidance in policy making. It is necessary because obtaining complete scientific certainty is often unrealistic. On the other hand, waiting for full certainty might not be prudent. In the 1970s and 1980s, the awareness regarding hidden costs of technological progress increased. Natural resources were perceived as limited resources, and a common understanding developed regarding the need to address unwillingly created risks of new technologies (Zander 2010). Ricci (2006) refers to an ancient principle of legislation, namely, Justinian’s “do no harm” as one of the conceptual origins of the Precautionary Principle. Many authors refer to the so-called Vorsorgeprinzip when explaining the initial conceptualization of the Precautionary Principle. “Vorsorgeprinzip” was a leading principle in the German Environmental Law of the early 1970s (Holdway 2009; Maguire and Ellis 2003; Tosun 2013). The Precautionary Principle was introduced to facilitate a cautionary approach in environmental policy. Initially, the German term was used in a broader sense than precaution alone, comprising a precautionary as well as a preventive approach. Later a distinction was made between preventive and precautionary concepts (see Trouwborst 2009).

In the 1980s and 1990s, the Precautionary Principle was integrated into several global or international documents. In the Rio Declaration on Environment and Development of 1992 (Annex 1, Principle 15), the Precautionary Principle was given as follows: “In order to protect the environment the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation” (United Nations Environment Programme, UNEP 1992).

Other legal documents mentioning the Precautionary Principle include the Convention on Biodiversity (Preamble), as well as the Lisbon Treaty 2007 amending the Treaty on European Union, Maastricht 1992. Article 191(2) refers to several policy principles, especially to the Precautionary Principle: “Union policy on the environment shall aim at a high level of protection... [and] shall be based on the precautionary principle and on the principles that preventive action should be taken, that environmental damage should as a priority be rectified at source and that the polluter should pay” (Commission of the European Communities, CEC 2000; Ricci 2006). Three other policy principles mentioned in this article of the European treaties are the preventive principle (taking measures to avoid harm and use resources diligently), the source principle (treating environmental damage as close to the source as possible), and the polluter pays principle (party responsible for the environmental damage carries the cost; Proelss 2016).

Even though the Precautionary Principle is widely integrated in international environmental law, there is no clear-cut definition. It neither represents a detailed operational procedure nor does it set a certain level of protection. It is just a guiding principle, e.g., for environmental law of the European Union (CEC 2000). In the Communication document on how to use the Precautionary Principle, it is specified that it should be applied for uncertain risks to human health and the environment if there is reasonable scientific basis for concern (CEC 2000). Measures

following the Precautionary Principle should be proportional with regard to the envisaged level of protection (excluding any risk at all is usually not possible). Actions based on the Precautionary Principle should be consistent in comparable situations, and they should be cost-effective. Also reviews at regular intervals should clarify whether new scientific information for an improved scientific risk assessment is available (Proelss 2016; von Schomberg 2006). For compliance with the CEC Communication, the attribution of the burden of proof should also be defined. This means it should be clarified whether the actions proposed are assumed to be harmful unless proven otherwise (Proelss 2016). The application of the Precautionary Principle in a decision-making process is independent from setting the appropriate level of protection. Establishing the appropriate level of protection is considered a normative decision in political context without direct link to the application of the Precautionary Principle (Holdway 2009; von Schomberg 2006).

Forms of the Precautionary Principle: Inaction, Action, and Burden of Proof

Depending on the context, there are different forms of the Precautionary Principle. The forms basically vary with regard to three aspects:

- How serious does the harm need to be to invoke the Precautionary Principle?
- How strongly is a reduction of uncertainty required?
- How strongly is the need expressed to take action?

So, key points of differentiation refer to harm, evidence, and action or measures. Many authors describe two basic forms of the Precautionary Principle, a weaker and a stronger version (e.g., Maguire and Ellis 2003; Tosun 2013). In summary, the weaker version indicates that uncertainty about adverse effects on environment or human health is no reason for noninterference. The stronger version on the

other hand indicates that uncertainty is a good reason to take action. Both versions represent extremes, but there are some gradations in between. Stewart (2002), for example, gives four forms, two of these represent weaker versions and two represent stronger versions of the Precautionary Principle. Science for Environment Policy (2017) describes a stronger, a weaker, and an intermediate form of the Precautionary Principle. The strong form corresponds to a situation where the policy principle is invoked due to a threat of harm although the cause-effect relationship is not fully clear (including lack of data, undetermined risks, and according to some authors also unknown risks). The weak form corresponds to circumstances where the policy principle is applied only in cases of serious and irreversible damage and lack of data as a source of scientific uncertainty. Measures corresponding to the strong form are often strict (e.g., bans), whereas for the weak form, measures commonly include risk management activities. Some authors also give an additional form of the Precautionary Principle, where the so-called burden of proof can be attributed to different actors, e.g., to the proponent of a potentially damaging action rather than to the population in the area (Morgera 2017). So if an actor likes to change a production process to produce a new chemical, for example, he/she would have to prove that the risk of the new production process is acceptable. The weaker form of the Precautionary Principle is more conservative of the status quo; the stronger form of the Precautionary Principle is more open to change processes. Figure 1 gives an overview of a strong and a weak form of the Precautionary Principle differing with regard to three key aspects (harm, evidence, and measures).

The Precautionary Principle: Supported and Controversially Discussed

As explained above, a number of environmental policy principles are used in legislation and decision-making. Among these policy principles, the Precautionary Principle is one of the most widely applied principles, and, at the same time, it is most

Precautionary Principle, Fig. 1 Overview of two basic forms, a strong form and a weak form, of the Precautionary Principle. Both forms vary with regard to three aspects

(harm, evidence, and measures; Garnett and Parsons 2016; Maguire and Ellis 2003; Science for Environment Policy 2017; Zander 2010)

intensely discussed (Holdway 2009; Paterson 2007). Decision-making about environmental risks regarding new chemicals or new technologies requires active contributions from stakeholders in legislation, policy, and risk management. However stakeholders might differ in their perception of risk and the perceived need for intervention. Discussion about the Precautionary Principle is mainly related to the issue that there is no detailed clear-cut definition of it. Some authors state that this policy principle is expressed very vaguely (Garnett and Parsons 2016; Stewart 2002; Zander 2010); other authors recall that the Precautionary Principle is no less vague than others (Sandin et al. 2002). So, the Precautionary Principle does not give a standard operational process description for decisions about interventions regarding complex and uncertain risks. However it favors intervention over doing nothing (Tosun 2013). Thereby the Precautionary Principle can help to protect human health and the environment (Mariqueo-Russell 2017; Zander 2010), but it also increases the need for a more transparent exchange of ideas

and risk management (Tosun 2013). Scientists and policy makers who favor the Precautionary Principle see this as an advantage when it comes to integrating the protection of human health and environmental resources into legislation and decisions. If ideas of stakeholders regarding harm, evidence, and measures are discussed and described in the decision-making process, transparency is guaranteed (Holdway 2009).

To give guidance on how to use the Precautionary Principle in EU legislative processes and decision-making, the EU issued a Communication on the Precautionary Principle (CEC 2000). The Communication outlines a framework for the application of the policy principle. It is expressed that the Precautionary Principle has a scientific basis, as it is applied after gathering information for a scientific risk assessment. Also guidance regarding the measures is given (they should be proportional to the level of protection, non-discriminatory, consistent, based on a cost-benefit analysis of the action and non-action scenario, and the evidence should be subject to review at regular intervals

(CEC 2000; von Schomberg 2006)). This guiding document can help to better apply the Precautionary Principle; however the application of the Precautionary Principle in practice has also caused controversial debate (Science for Environment Policy 2017).

A review of the use of the Precautionary Principle in the European Union in practice has shown that even though judicial decisions largely follow the EU guidance, the application of the Precautionary Principle in legislative decision-making is not always consistent (Garnett and Parsons 2016). However inconsistency is rather linked to the practical application than to the policy principle itself.

Critics of the Precautionary Principle state that it potentially hampers innovation or could be misused to set up barriers for the introduction of new technologies (CEC 2000; Paterson 2007). However, sometimes scientific results are interpreted in different ways between countries. In the discussion about the import of genetically modified crops from the United States into the European Union, the EU adopted a cautionary (or in the view of critics also more protectionist) attitude due to different interpretations of the Precautionary Principle in the United States and the European Union. The World Trade Organization Agreement on Sanitary and Phytosanitary Measures is another example for country-dependent approaches to dealing with uncertain risks. In this agreement it is stated that in case of scientific uncertainty, sanitary or phytosanitary measures can be taken and need to be reviewed regularly (Tosun 2013). So the focus here is on implementing measures in spite of a current lack of scientific evidence.

Outlook: Precautionary Principle and Sustainable Management in Response to Climate Change

On the one hand, a prudent approach to legislation seems useful and is widely supported especially with regard to the need to manage limited environmental resources sustainably. On the other hand, environmental policy and legislation need

to give room to innovative technologies, e.g., to better cope with the challenges of climate change. So the Precautionary Principle is important for policy and legislation in the future. One of the largest future challenges will be to find and implement viable measures to address climate change. As far as major global anthropogenic effects on the earth's climate are concerned, global consensus was reached on the fact that the anthropogenic contribution to global warming is significant and that the effects are serious (Grassl and Metz 2013; Intergovernmental Panel on Climate Change, IPCC 2007). However, climate change is a complex issue, e.g., with regard to the unequal distribution of effects across different countries and between generations. Also, it is difficult to establish direct causal relationships for specific emissions and effects on a small scale. So there is uncertainty about the detailed effects of climate change at a specific location and a specific time. One option to facilitate decision-making about climate change mitigation and adaptation is to follow a precautionary strategy (Frisch 2018). While setting a clear temperature limit in spite of scientific uncertainty regarding specific impacts can be seen as a precautionary approach (Grassl and Metz 2013), controversy about suitable measures for the mitigation of climate change effects also might require precautionary decision-making processes (Grassl and Metz 2013; Reynolds and Fleurke 2013). Applying the Precautionary Principle well to complex phenomena like climate change means to use the principle as guidance step by step. These steps comprise identifying serious harm, recognizing uncertainty, and investigating alternatives such as reduction of emissions or reduction of CO₂ concentration by climate engineering. Here it should be taken into account that the alternatives also pose potential risks to human health and the environment. The steps also include a discussion of the distribution of responsibility to demonstrate the safe use of new technologies. Finally stakeholders should ensure that decisions are subject to review and measures are proportionate (Reynolds and Fleurke 2013). The Precautionary Principle can be an important tool to address complex challenges like climate change because it integrates

uncertainty, complexity, and the difference of values among different stakeholders. Involving stakeholders is a good option to adapt the Precautionary Principle to context and challenge (Karlsson 2004; Paterson 2007). The Precautionary Principle as outlined in international agreements such as the Rio Declaration on Environment and Development can give direction for a more sustainable management of resources.

Summary

The Precautionary Principle is an environmental policy principle. It can help to take action, e.g., by policy makers when there is possible harm to the environment or human health, even though conclusive scientific evidence is not yet available. There are two basic forms of the Precautionary Principle, a stronger form (“uncertainty justifies action”) and a weaker form (“uncertainty does not justify inaction”), which differ with respect to the definition of harm, the interpretation of scientific evidence, and the need to take action. On an international and national level, there are numerous examples for the use of the Precautionary Principle in agreements and decision-making. However there is some discussion regarding how and when to use it. The Precautionary Principle can provide guidance when addressing enormous challenges like climate change or the sustainable management of limited natural resources.

Prequalification Processes (Clients Demanding of Potential Suppliers)

Jellie Molino

University of Turin, Turin, Italy

Synonyms

Initial selection; Preselection; Presolicitation; Pre-tender; Shortlisting

Definition

Assessment of prospective or potential suppliers, contractors, or consultants using pre-approved criteria such as eligibility, financial ability, technical capability, etc., to establish a list of suppliers, contractors, or consultants that meet the minimum criteria for a specific contract or a regular project before inviting them to submit their solicitations, proposals, tenders, or bids (UN 2020; IDB 2019; WB 2018; ADB 2018; UNCITRAL 2014; EBRD 2012).

Introduction

An ideal procurement system, whether from the public or private perspective, is one when a procuring entity (organization in need of goods, services, or construction works) can easily get its needs for goods, services, or works from the best of the available suppliers, consultants, and contractors in the market, and adopting a pre-qualification process is one of the available strategies in “choosing amongst the prequalified, the ones best qualified to be solicited” (UNCITRAL 2011).

While purchasing activity of public entity is the same as that of the purchasing departments in businesses, the latter has more flexibility since public procurement uses government funds; hence, it must comply with specific procedures in the applicable government regulations while

Premium

- Bonuses (Employee for Performance)

adhering to international state agreements, e.g., the World Trade Organization Public Procurement Agreement (WTO-GPA), or loan/grant agreements, e.g., sovereign projects of multilateral development banks (MDBs).

This contribution, however, is limited to prequalification process in public procurement, which private purchasers may use as guide in understanding the minimum requirements and procedures for prequalification process in applying for a government project or contract. Although it also excludes any prequalification process in case of public-private partnership (PPP), it may still be useful as guide in projects financed by MDBs that have similar guidelines for procurement projects and PPP projects such as the Asian Development Bank (ADB), European Bank for Reconstruction and Development (EBRD) and the Inter-American Development Bank (IDB).

In public procurement, prequalification should be differentiated from preselection (e.g., Article 49 of the 2011 UNCITRAL Model Law on Public Procurement) or presolicitation (e.g., presolicitation notices and conferences under the US Federal Acquisition Regulation) (Cibinic et al. 2011).

In prequalification, all prequalified suppliers or contractors may present submissions/offers/bids/tenders (UNCITRAL 2014; IDB 2019; ADB 2018).

In the case of preselection, the 2011 UNCITRAL Model for Public Procurement (UNCITRAL Model Law) explains that the maximum number of prequalified suppliers or contractors that will be permitted to present their submissions must be already indicated in the preselection proceedings (i.e., the preselection notice must indicate, for example, that the minimum suppliers or contractors that will be “prequalified” are the first three most qualified suppliers or contractors). The maximum number of participants that will be invited in the preselection proceeding is also indicated (UNCITRAL 2014). While both prequalification and preselection processes use the “pass or fail” qualification criteria in the evaluation of prospective or potential suppliers or contractors (UN 2020; WB 2018; ADB 2018; UNCITRAL 2014; EBRD 2012), the preselection

procedure requires an additional “competitive” requirement, usually a ranking, in the establishment of the maximum number of suppliers of contractors (e.g., the preselection involves, after a pass/fail examination, a ranking against the qualification criteria and the selection of the best qualified up to the established maximum) (UNCITRAL 2014). In short, preselection is more restrictive than prequalification as it provides both the minimum and maximum numbers of “preselected” (i.e., usually, the best of all the prequalified) suppliers or contractors to be invited to a solicitation, offer, bid, or tender.

Presolicitation is commonly used in the United States (i.e., presolicitation notice under the US Federal Acquisition Regulation, 48 CFR § 5.204) (GSA, 2019) as a procurement vehicle to develop competition in advance to prospective procurement through the use of presolicitation notices (e.g., general procurement notices informing potential competitors of the intention to conduct a procurement using other than competitive procedures) or presolicitation conferences (i.e., early exchanges with industry when competitive negotiations are employed instead of open and competitive bidding) (Cibinic et al. 2011).

Just like prequalification, presolicitation invites potential “qualified” competitors to submit an expression of interest in response to a presolicitation notice, and the procuring entity has the obligation to include all the interested competitors (those who submit a timely expression of interest in response to the presolicitation notice) in the issuance of the tender or solicitation through either a request for quotation (RFQ) or a request for proposal (RFP) (Id.). Presolicitation, however, gives the procuring entity an obligation to evaluate a single response to a presolicitation notice for a possible sole source award (Id.), which is not the case in a prequalification process, unless it is an embedded stage in a restrictive procurement procedure, e.g., competitive dialogue or competitive negotiation, under the European Union (EU) procurement regulations (EC 2018b).

A similar practice, but referred to as “pre-tender market consultation,” is observable in OECD countries like Latvia (through its website) and New Zealand (“Meet the buyers events for certain

categories of supplies”, e.g., small and medium enterprises), a practice in which “sellers send their expression of interest to meet with particular buyers via a simple web form” and “buyers shortlist businesses they want to meet” (OECD 2019), albeit no contract award can be made from an invitation or notice to a pre-tender market consultation, unlike in the US notice to a presolicitation.

This contribution, however, focuses its discussion on the use of prequalification process as a formal stage in the selection of potential suppliers, contractors, and consultants. It includes the usual procedures for registration and qualification of suppliers such as the supplier registration system or prequalification system for suppliers, which provides the minimum requirements for supplier registration to minimize the qualification procedures (Article 59 (5), Directive 2014/24; EC 2018a). Any procuring entity may maintain a supplier registration system that allows all registered (“prequalified”) suppliers to participate in a public procurement. Nonetheless, such registers cannot be used as substitute for the “prequalification process” under open and competitive solicitation/bidding/tender using multi-staged procurement (EBRD 2012) nor the “prequalification stage” in restrictive or selected solicitation/bidding/tender (EC 2018a).

The prequalification process, also known as “initial selection process” (WB 2018), that is included in this contribution refers to the “generally acceptable” (i.e., common requirements or standards in prequalification process irrespective of jurisdiction) process of shortlisting applicants in the procurement of goods, works/construction, or consulting services to ensure that only those with appropriate and adequate capacity, capability, and resources are invited to submit their bids, proposals, or tenders, using the standard guidelines and requirements for prequalification in the UN Procurement Manual (UN 2020); the Inter-American Development Bank’s Policies for the Procurement of Goods and Works financed by the Inter-American Development Bank (IDB 2019); the World Bank Group Procurement in Investment Project Financing for Goods, Works, and Non-consulting and Consulting Services (WB

2018, as revised in 2018); the Asian Development Bank Prequalification Guidance Note on Procurement (ADB 2018); the European Bank for Reconstruction and Development Guidance Notes on the Prequalification of Tenders (EBRD 2012); the EU Directives on Public Procurement 2014; the US Federal Acquisition Regulations on presolicitation notices (48 CFR § 5.204) and prequalification (48 CFR § 236.272); and the 2011 UNCITRAL Model of Public Procurement (UNCITRAL 2011) and its Guide to Enactment (UNCITRAL 2014).

Purpose of Prequalification Process

Prequalification process is intended to identify, at an early stage, suppliers or contractors with qualifications and experience that are suitably qualified to perform a specific contract (UN 2020; IDB 2019, WB 2018; ADB 2018; UNCITRAL 2014; EBRD 2012) and, thereby, minimize the risk of non-performance (ADB 2018; EBRD 2012). This stage may also be considered as the beginning of the formal procurement process to select a private sector provider (UN 2020). Only vendors/suppliers/contractors that meet established criteria are invited to a solicitation, tender, or bid (shortlist) (Id.).

Application of Prequalification Process

Prequalification process constitutes as an exception to the general rule on public and unrestricted solicitation (UNCITRAL 2014). Prequalification exercises apply in instances where there is a need to limit the list of invitees (bidders/offerors/tenderers) (WB 2018), by narrowing down the number of submissions that a procuring entity will evaluate from those qualified suppliers or contractors (UNCITRAL 2014).

In fact, procuring entities use prequalification process as a tool to facilitate the effective procurement of relatively complex subject matter (Id.) or high-value goods, construction, or services (e.g., the need for custom-designed equipment, plant, specialized services, some complex information

and technology, procurement under turnkey, design, and build), or management contracting (WB 2018; ADB 2018; EBRD 2012), and as a necessary requirement for innovative works or in other cases in which the high cost of preparing detailed bids/tenders/offers could discourage competition (IDB 2019).

In some cases, prequalification process is also used in purchases of a relatively low value but of a highly specialized nature (UNCITRAL 2014) or as basis of framework agreements (EBRD 2012) (i.e., an agreement between the procuring entity and the selected suppliers concluded upon the completion of the first stage of the framework agreement procedure, qualification of suppliers/contractors) (UN 2011) or in cases “where the number of bidders which are likely to be qualified is high or where a standing list of prequalified bidders is to be established for group or contracts to be awarded over time” (ADB 2018).

The UN Procurement Manual categorizes the use of prequalification process in at least three instances:

- a. The high costs of preparing detailed bids could discourage competition (such as custom designed equipment, design and build projects, or specialized services).
- b. The requirement involves complex technical components for which the vendor needs to have minimum technical capability and capacity to complete the works to the required quality standard such as construction works.
- c. As determined necessary to achieve the best outcome for the procurement process for highly complex needs (UN 2020).

In most procurement systems, prequalification process is “optional and should be used for ‘fit-for-purpose’ basis” (ADB 2018) albeit may be used regardless of the method of procurement used (UNCITRAL 2014). Nonetheless, “not all EU Member States used the prequalification process regularly” due to “lack of standard tender documents and contract forms” and “unnecessary additional effort from both the contracting entity and tenderer” (Niewiadomska et al. 2011).

It is worth to note, however, that prequalification process in the EU procurement system is already embedded in four of the five procurement procedures under the 2014 EU Directive on public procurement: (1) restrictive procedure (i.e., a two-stage process where only preselected tenderers may submit tenders on the second stage), (2) competitive procedure with negotiation (i.e., shortlisting of at least three candidates who are invited to submit an initial tender and then negotiate), (3) competitive dialogue (i.e., the use of competitive dialogue among shortlisted operators based on their capacity to perform the contract), and (4) innovation partnership (EC 2018a), i.e., a three-stage procurement process that involves prequalification, negotiation, and delivery in a project for development of innovative solution with corresponding resulting innovative products, services, or works (Valenza et al. 2019). It is not commonly used in the EU open procedure since all interested operators can submit tenders and all tenders must be considered without any prior selection process (EC 2017; OECD 2019), except in the case of dynamic purchasing system (DPS), a fully electronic system used by contracting authority for purchases of commonly used works, services, or goods that is open to any tenderer that satisfies the selection criteria (prequalification criteria) (Valenza et al. 2019). Any tenderer, however, can apply for prequalification to join in DPS at any time (Id.).

The US Federal Acquisition Regulation authorizes prequalification of sources only when it is necessary to ensure timely and efficient performance of critical construction projects by providing a list of sources that are determined to be qualified to perform a specific construction contract and limiting the offer to those with proven competence to perform the required manner (48 CFR § 236.272).

Requirements for Prequalification Process

The first requirement for the use of prequalification process is the approval of its use by the procurement authority or the head of the

contracting activity (UN 2020). It must be specifically included with rationale or justification in the procurement plan, source selection plan, or acquisition plan of the procuring agency (Id.). Invitations for prequalification must be published or advertised in the relevant agency website and any other relevant media (Id.). Charges for the prequalification documents and development costs (including consultancy fees and advertising costs) are allowed provided the cost should be limited to minimal charges (UNCITRAL 2014) or “nominal fee for the cost of reproduction and of dispatching of the documents by courier” (EBRD 2012).

Procedures for Prequalification Process

Prequalification process begins with an invitation for expressions of interest (EOI) (UN 2020) or an invitation for prequalification (IFP) (WB 2020). The EOI/IFP notice should include the relevant information for the prospective bidders/offerors/tenderers to consider:

- Basic information about the project/contract (i.e., name of the procuring entity, including contact details, number of contract, and/or brief description of the project/contract, details, e.g., deadline for submission of EOI other prescribed forms)
- Special conditions/requirements of the project/contract (scope of work)
- Evaluation criteria, i.e., eligibility, experience, financial condition, etc., and their relative weights (qualification criteria and requirements)
- The procedure for final selection (prequalification procedures) (WB 2020)

The following are the common procedures for prequalification process:

1. The process guarantees that solicitation or tender documents, i.e., requests for proposals (ROP), requests for quotations (ROF), and invitation to bid (ITB), are issued only to vendors/suppliers/contractors with adequate

capabilities and resource. (UN 2020; WB 2018; ADB 2018; UNCITRAL 2014; EBRD 2012). Adequate time must be allowed for potential vendors/suppliers/contractors to prepare responsive applications or expression of interest (UN 2020). For UN-funded projects, the period between the invitation for prequalification and the deadline for submission of a response shall be “no less than 10 working days” (Id.), but, in most cases, it is usually “consistent with the WTO-GPA provisions on the submission of applications,” i.e., not less than 25 days from the date of publication of notice (EBRD 2012).

2. In prequalification, minimum requirements are normally assessed on a pass/fail basis against published criteria (UN 2020; WB 2018; ADB 2018; UNCITRAL 2014; EBRD 2012). All applicants or interested competitors that substantially meet the minimum qualification requirements are invited to submit a tender, a bid, an offer, or a quotation (Id.). “Scorable” prequalification criteria, i.e., criteria related to the special requirements of the project that are scored against a predefined scoring scale for purpose of comparing the relative capabilities of all applicants, may be added to the pass/fail prequalification criteria (ADB 2018).
3. The assessment of an applicant’s qualifications does not usually take into consideration the qualifications of other firms such as its subsidiaries, parent entities, affiliates, subcontractors, or any other firm different from the firm that submitted the prequalification application (ADB 2018; WB 2018), except in case when one of the requirements in the notice of prequalification includes a specialized process, e.g., construction operation that requires installation and commissioning of specialized engineering systems or underwater repair work, and the qualifications of the specialist from subcontractors are not available in-house, which could result in disqualification of the applicant (EBRD 2012).
4. At the end of the prequalification process, the procuring entity is required to inform all applicants or interested competitors of the results of the prequalification (IDB 2019; WB 2018;

- ADB 2018; EBRD 2012). The invitation to submit a bid or an offer or tender to a prequalified supplier/vendor/contractor shall include the names of all prequalified suppliers/vendors/contractors (EBRD 2012).
5. Prequalification procedures are conducted using objective terms and conditions (WB 2018) that are fully disclosed to participating suppliers or contractors; they are also designed to ensure a minimum level of transparency and to facilitate the exercise by a supplier or contractor that has not been prequalified of its right to challenge its disqualification (UNCITRAL 2014).
 6. Complaints challenging the terms of prequalification/initial selection documents are allowed within a specific period, usually at least 10 business days prior to the deadline for submission of bids/proposals/tenders (WB 2018).

It is worth to note that prequalification is “distinct from the bid process” (ADB 2018; EBRD 2012); hence, it is not intended to cover any aspect of the proposal for the project or factors related to the indicative contract (UNCITRAL 2014). These elements, i.e., price and merits of the specific tender (EBRD 2012) and technical and financial aspects of specific bids (ADB 2018), are considered at the later stages of the procurement process.

Qualification Criteria

Prequalification criteria must adhere to the basic principles of public procurement or its “three overarching principles” – competition, transparency, and integrity (Schooner 2002); and since prequalification may “limit competition,” it requires that the qualification criteria must be not only “appropriate for the purposes of the specific procurement” (UNCITRAL 2014) but also objective (i.e., capable of objective assessment and application), proportionate, non-discriminatory (CCH 2019) (i.e., equal or equitable treatment) (UNCITRAL 2014), fair, and transparent (EBRD 2012).

Moreover, the prequalification criteria must not “inhibit competition nor limit the number of eligible applicants” through an “overly strict or excessive criteria, i.e., beyond what is strictly necessary for the needs of the contract... or overly lenient results to an excess of unsuitably qualified applicants” (ADB 2018).

The typical qualification criteria include eligibility or legal status (i.e., registration, nationality/citizenship; for MDB-funded projects, e.g., ADB, EBRD, IDB, WB, eligibility includes affiliation to any of their member states), general and particular experience (i.e., historical contract non-performance, contract of similar size and nature, current obligations and pending awards), technical capability (i.e., management capabilities, personnel capabilities, average annual turnover equipment availability, manufacturing capacity, workplace health and safety management system), financial situation/position, and litigation history (UN 2020; IDB 2019; WB 2018; ADB 2018; UNCITRAL 2014; EBRD 2012). Sustainable procurement considerations, i.e., social and environmental sustainability, may also be applied in the prequalification of firms (WB 2018).

Advantages of Prequalification

Prequalification provides advantages both to the procuring entity and the prospective bidders/offers/tenderers (ADB 2018; EBRD 2012).

For procuring entity and prospective suppliers/vendors/contractors, prequalification allows them to:

- Screen potential bidders/offers/tenderers for contract specific requirements and capability (ADB 2018; EBRD 2012)
- Reduce or eliminate the need to evaluate bids/offers/tenders from unqualified bidders/offers/tenderers (ADB 2018)
- Enable prospective bidders/offers/tenderers to understand minimum requirements, providing them with the opportunity to join with other prequalified bidders/offers/tenderers to bid/submit offer/tender for a contract (Id.)

- Expose potential conflicts of interest of prospective bidders/offerors/tenderers with other parties involved in the prequalification (Id.)
- Enable identification of prospective bidders/offerors/tenderers eligible for domestic preference, where this is applicable (ADB 2018; EBRD 2012)
- Enabling prospective bidders/offerors/tenderers who may be insufficiently qualified on their own to avoid the expense of tendering or to enter into a joint venture, consortium, or association, which may have a better chance of success, or consider working as a sub-contractor on a project (EBRD 2012)

For procuring entities, prequalification enables them to:

- Alter the procurement strategy in response to the level of interest from qualified prospective offerors/bidders/tenderers (ADB 2018)
- Select potential contractors/suppliers, who meet project-/contract-specific qualification criteria and, therefore, are deemed to be capable of performing the project/contract satisfactorily (EBRD 2012)
- Assess the interest generated by the project among qualified firms and to make any necessary adjustments to the procurement process (including, in particular, the evaluation methodology, the conditions of contract – sharing of risk, payment terms, liquidated damages, warranty, or completion times – which may be perceived as onerous by potential bidders/offerors/tenderers) (Id.)
- Reduce the amount of work and time involved in evaluating tenders from unqualified contractors or suppliers (ADB 2018; EBRD 2012)
- Encourage local firms to form joint venture with other local or foreign firms, thereby benefiting from their resources and experience (EBRD 2012)
- Eliminate or significantly reduce problems associated with low prices submitted by bidders/offerors/tenderers of doubtful capability (Id.)

On the other hand, prospective bidders/offerors/tenderers benefit from prequalification process by:

- Avoiding the expense of bidding if not sufficiently qualified (ADB 2018)
- Building confidence that unqualified competitors will be excluded from submitting unrealistically low bids (Id.)

Moreover, the well-qualified firms may also price their tenders with the knowledge that they will be competing with other qualified tenderers that meet the appropriate minimum competence criteria, while they are assured that competitors lacking the necessary qualifications will be excluded from tendering, thus encouraging leading contractors or suppliers to tender (Id.).

Disadvantages of Prequalification

Potential disadvantages of prequalification include that (i) it may increase the total procurement process time and (ii) it may facilitate corruption and collusion among applicants, since the identification of prequalified applicants will be made public (ADB 2018).

Principle of Solidarity

Borna Jalsenjak

Luxembourg School of Business, Luxembourg,
Luxembourg

Zagreb School of Economics and Management,
Zagreb, Croatia

Definition

The principle of solidarity is a socio-ethical and political concept which states that it is fair and just that benefits and obligations are justly shared between members of the society.

Description of the Principle of Solidarity

The name of the principle is derived from a French word *solidarité*, meaning solidarity or support. In modern Europe, the word solidarity gained much attention in the 1980s, thanks to social and workers' movement *Solidarność* in Communist Poland which was led by Lech Wałęsa and which played an essential role in the advocacy of workers' and social rights.

The fundamental idea behind the principle of solidarity is a Christian understanding of a person as an individual substance of rational nature which has intrinsic value. Interconnected persons create societies. Due to interconnectedness, rationality, and intrinsic value belonging to a person,

people bear the responsibility for the community. In turn community, as a group of persons, has a responsibility to cater to a person. In essence, the principle bridges the opposing sides of individualism and socialism by understanding obligation from two starting positions: the person and the community. Looking from two starting perspectives makes the solidarity principle different from individualism which starts from persons and from socialism which starts from the collective. Also, the principle of solidarity is not aimed against competition. It does not advocate for some weak sentimental. What it is aimed at is emphasizing the responsibility of individuals for the whole. Societies can function properly only if individuals understand that for their own good and progress, it is necessary to take an active part in accomplishing the common good. This taking part often consists of sharing part of resources, and sometimes it entails limiting individual perhaps unrealistic aspirations. In the Christian tradition, the principle of solidarity together with the principle of the common good, the principle of subsidiarity, the principle of freedom, democratic principles, and private property forms a core of social principles which are underpinning moral societies.

The Pontifical Council for Justice and Peace (2004) in *Compendium of the Social Doctrine of the Church* (§ 194) emphasizes that ties uniting men should be recognized, as well as the freedom for common growth which all men share and can participate in. The idea is further developed like this: "(...) into the willingness to give oneself for the good of one's neighbour, beyond any individual or particular interest" (§ 194). It also means that people are required to recognize that they are in debt to the society because of all living conditions societies provide and that these conditions should be preserved for future generation so that they may as well partake in the gift of the society (§ 195). This principle has to be manifested in the communities since the collective can only function adequately if an individual feels a lasting commitment to the whole, but the whole also acknowledges an individual and its freedom and value. In the

Catholic social teaching, this principle is especially noticeable in the encyclical letter by the Pope John XXIII (1963) *Pacem in Terris*.

As a political concept, solidarity has a long history in Europe, but it is not always clear what it means; this mainly refers to the notion of European solidarity which is used in political discourse in many different contexts (Gainer 2017; Schmale 2017). For example, the principle might be evoked to rationalize why does society, through various methods of taxation, redistributes wealth in order that people who are worse off in that society receive aid so they can live their life with dignity aligned with their intrinsic value as persons. Another context in which principle of solidarity is used is globalization, it is often being stated that countries should act in accordance with the principle of solidarity and it should be avoided that one country takes advantage of another. Also, in many countries, various versions of social security policies are based on the principle of subsidiarity. Furthermore, the principle of solidarity might be evoked to call for groups or individuals in a certain community to help others when they face certain dangers or have suffered harm.

The principle of solidarity, besides values of lasting peace, unity, equality, freedom, and security, is one of the key ideas on which the European Union has been built (EurWORK 2011). The principle is mentioned explicitly in Articles 2 and 3 of the Treaty of the European Union (Consolidated version of the Treaty on European Union 2012). In Article 3, it is highlighted that the European Union is going to promote solidarity among member states. The principle is also present in many European civil law systems, and in them, it usually has two connotations (Steinvorth 2017, p. 9). The first one is that resources of people or organizations not responsible for the damage are sometimes used to help repair them. The second context in which solidarity is used is when help is called for by partner parties if some difficulties arise which were previously stipulated in the agreements. For example, the European Foundation for the Improvement of Living and Working Condition (EurWORK 2011) states that the principle of

solidarity “is often used in the context of social protection” and that “Implementation of the Solidarity Chapter of the EU Charter aims to build a bridge between programmatic solidarity rights (social and economic rights) and justiciable civil and political rights. Justiciable rights equate to effective and enforceable rights. The challenge is to establish clearly justiciable solidarity rights (e.g. trade union freedom of association, information and consultation, collective bargaining and collective action), and, further, to develop and implement programmatic social and economic solidarity rights: e.g. health, education, etc.”

Principle of Subsidiarity

Borna Jalsenjak
Luxembourg School of Business,
Luxembourg, Luxembourg
Zagreb School of Economics and Management,
Zagreb, Croatia

Definition

The principle of subsidiarity is a socio-ethical and political concept which is based on the idea that decisions should be made on the lowest possible level of an organizational hierarchy. If the lowest organizational level is not in a position, or objectively cannot make a decision, the authority is transferred to the first higher level. Principle of subsidiarity can be looked at as sort of a defense mechanism against interference of higher-level authorities in matters concerning smaller communities, private concerns, and individuals.

Description of the Principle of Subsidiarity

The name of the principle of subsidiarity is derived from a Latin word *subsidium*, meaning help, relief, or reinforcement. This word was used for units in the Roman army who were tasked to give support to the central fighting units if the first line needed it (Thorne 2011). The principle of subsidiarity is a prominent principle of social ethics and is found in the Catholic social teaching and is especially emphasized in the encyclical letters *Rerum Novarum* (Leo XIII 1891) and *Quadragesimo Anno* (Pius XI 1931). In the *Compendium of the Social Doctrine of the Church* (Pontifical Council for Justice and Peace 2004, § 186), principle of subsidiarity is explained by stating that it is unfair to assign to the higher authority something that can be done by subordinate organizational part.

Similarly, on an individual level, it is wrong to take away from individuals something they can

accomplish by themselves. To do that would mean that social body would absorb the individual. The reason for the Catholic tradition of arguing in favor of subsidiarity is because the Church fought to protect against socialism but also to ensure that capitalism does not take advantage of an individual. In the background of such thinking is the idea that the full development of an individual's potential is human good (Follesdal 2013). Also, from this principle of subsidiarity follows that every norm, law, or a process in the society should be aimed at supporting individuals and attaining the common good.

The primary purpose of the principle of subsidiarity is determining the capability of a particular entity, or part of a society, in achieving the common good. In other words, the principle of subsidiarity is the defense of free initiative in society. Thus, society can take on itself only those activities which individuals, or its smaller parts, cannot achieve by themselves. Government of any kind should not take away individual's responsibility on governing his life. The principle of subsidiarity is created not to stand opposite to the principle of solidarity because what the principle of subsidiarity actually stands for is the demand of individuals to invest as much effort as possible in their social life and activities. Said in different words, since the society uses its authority and power for action, the principle of subsidiarity limits and directs how much power can be used and in what circumstances. Social authority should only be used to resolve issues which members of the society are unable to resolve by themselves. As such, the principle of subsidiarity protects individuals from totalitarian states, advocates federalism and decentralization, and emphasizes rights of minorities, small communities, and individuals opposed to rights of the majority.

In essence, the principle of subsidiarity can help to determine when and what kind of intervention is needed from a position of a higher organizational unit in the dealings of a unit on the lower level in the organization. All unnecessary intervention is considered to be unproductive because on one hand the higher authority will spend its resources in an

unnecessary way and on the other hand, in doing so, lower organizational units will not reach their full potential.

In the context of a contemporary political organization, the principle of subsidiarity will advocate in favor of federalism and decentralization. For example, in the European Union, the principle of subsidiarity was formally recognized in the Maastricht Treaty. In the EU the principle of subsidiarity is used “(…) to guarantee a degree of independence for a lower authority in relation to a higher body or for a local authority in relation to central government. It therefore involves the sharing of powers between several levels of authority, a principle which forms the institutional basis for federal states” (Panizza 2018).

Examples of Possible Use of the Principle of Subsidiarity

Principle of subsidiarity can be used to call for or to justify many decisions in different areas of social life. For example, the principle of subsidiarity can be used in order to stop government from ordering a privately owned business to make a certain decision. It can also be used to argue against subsidizing a certain company if the company should be able to resolve matters it is facing on its own. In addition, the principle of subsidiarity can be evoked in everyday situations if an intervention from a higher authority, in activities of a lower organizational unit, is called for. For example, in the workplace context, micromanagement is often looked at as a wrong approach to management. The individual which is being micromanaged by a higher authority can never develop enough to face and resolve challenges that should be solvable on that level, and the activity itself often is the cause of much frustration. On the other hand, the higher-level authority is using its limited resources on something that is fundamentally counterproductive.

PFI

Definition

Public-Private Partnerships (PPPs) are an alternative way of traditional public sector supplying that constitutes and make new assets. PPPs' most widely used type is the Private Finance Initiative (PFI), which can be defined as financing public projects through private sector investment (Starodubtseva 2015). PFI is used as a financial instrument to finance off-balance-sheet public projects for notifying public debt and includes projects/services, such as schools, hospitals, road construction, prisons, highways, leisure centers, bridges, tunnels, sports facilities, infrastructure. The purpose of PFI was to increase collaboration between the private and the public sectors (Allen 2001; Eaton and Akbiyikli 2005; The House of Commons Committee of Public Accounts 2018; HM Treasury 2019). PFIs were officially used in the UK and spread fastly from there and copied to other countries (Hodge et al. 2017). The use of PFIs increased after 1997 and PFI and its variants are used in many countries today such as Austria, Greece, Portugal, Ireland (Ismail and Rashid 2007; Barlow et al. 2010; The House of Commons Treasury Committee 2011).

Private Finance Initiatives

The private sector has always supplied goods and services to the public (Eaton and Akbiyikli 2005). Governments around the world have tried to increase the engagement of the private sector in providing public services in many different forms such as privatization, private finance for social infrastructures, and contracting out of services (Hall 1998). Privatization is considered as one of the most significant economic policy reforms since the 1970s (Clifton et al. 2006). The UK government is one of the pioneers in privatization (Grout 1997), and during Thatcher's government, these privatizations became widespread. The aim of her government was to create more private-sector involvement in the public sector. In 1992, the UK Chancellor of the Exchequer Norman Lamont explained that PFI was about "ways to extend the range for private

financing capital of projects." PFIs continued to expand under the UK's labor government in 1997, and the UK's coalition government of 2010 also supported this method as a way of financing projects in infrastructure (Eaton and Akbiyikli 2005; The House of Commons Treasury Committee 2011). PFIs formally began in the UK (Pollitt 2000; Khaderi and Abd Shukor 2016), but today PFI and its several types have been increasingly used in many countries (Akintoye and Kumaraswamy 2016; Barlow et al. 2010; Ismail and Rashid 2007). Although PFI continues to be used in many countries, in the 2018 budget negotiations in the UK, Finance Minister Philip Hammond said that he will remove PFI for future construction works. He stated that he made this decision because there was a potential risk to the government budget of PFI. With this decision, it was decided to suspend the PFI, which was signed in 1998 and has a validity of 52 years, in a way that does not include ongoing projects. In short, PFI will disappear completely in the UK by 2050 (Booth 2018). But the reason why the government does not terminate existing contracts is the high compensation payments in the contracts. PFI was criticized by the committee because of these clauses in the contracts, by the budget account office for posing a risk to the government budget (The House of Commons Committee of Public Accounts 2018).

PFI is a type of procurement that involves the private sector operating the design, build, financing, and operation (DBFO) of public facilities. It is a method where the public sector makes a contract with the private sector to build and operate public projects and uses the PFI for a period of 25–30 years (depending on the type of the project) to make the projects. In these projects, the public sector rents the project from the private sector while making annual payments without owning the asset. These annual payments involve interest repayments and debt, asset preservation, maintenance and services, shareholder dividends, and sometimes other services (HM Treasury 2019; House of Commons Committee of Public Accounts 2018; Starodubtseva 2015). PFI projects consist

of three main parties: (i) The Awarding Authority, (ii) The Special Purpose Vehicle (SPV), and (iii) Third-Party Funders. The Awarding Authority can be a local authority or government agency who is responsible for the procurement of the Project. Secondly, SPV is a private sector consortium that is responsible for the completion of the public project from the beginning of the contract to the end and also is the legal owner of the privilege granted by the public. Lastly, Third Party Funders represent bank loans, equity, or bonds (Alshawi 2009). Figure 1 explains the PFI process.

In addition, there are different arguments on whether PFI provides value for money. Supporters of PFI debated that PFI is not only about borrowing money from private companies but composing a structure for better value for money with the help of innovation and management skills of the private sector and transferring risk from the public sector to the private sector (Grout 1997; Eaton and Akbiyikli 2005; Akbiyikli et al. 2011; Khaderi and Abd Shukor 2016). On the other hand, critics stated that PFI is an expensive method of financing public services. PFI projects have long lifetimes, which brings supplemental and unforeseen costs so there is uncertainty about whether they deliver value for money (Froud 2003; Edwards et al. 2004; Coulson 2008).

Real-Life Examples of PFI Projects

PFI includes projects and services that provide benefits to the public sector. According to the HM Treasury Report announced on March 31, 2018, some of the current PFI projects in the UK are shown in Table 1.

Advantages and Disadvantages

PFI can create real benefits in the shape of business profit. PFI projects provide private sector involvement in the public sector, and in this way the public and private sectors can work together. The main aim of PFI is to increase capital flow to

Private Finance Initiative, Fig. 1 A step by step guide to the PFI process. (Source: Based on Treasury Taskforce, Step by Step Guide to the PFI Procurement Process 1999, retrieved from Allen (2001))

projects by using the private sector's money and skills (Eaton and Akbiyikli 2005). Furthermore, through PFI projects, a substantial amount of business risk is transferred from the public sector

Private Finance Initiative, Table 1 Some of the current PFI projects in UK

Project name	Department	Sector	Period of contract (years)	Capital value (£m)
Barnsley Schools PFI	Department for Education	Schools (Non-BSF)	25	47
Bromsgrove Schools PFI	Department for Education	Schools (Non-BSF)	31	64,4
Oldham Sheltered Housing PFI	Ministry of Housing, Communities and Local Government	Housing (HRA)	30	108
Suffolk FRS Serviced Accommodation PFI Project	Home Office	Emergency Services	27	18,8
PFI Eastbrook	Department for Environment, Food and Rural Affairs	Offices	30	18,2
PFI Nursing Homes (Farm Lane)	Department of Health and Social Care	Social Care	25	4,7
Gloucestershire – Community Fire Safety Project	Home Office	Emergency Services	26	25,9
Royal Stoke University Hospital	Department of Health and Social Care	Hospitals and Acute Health	38	415,1
Peterborough City Hospital	Department of Health and Social Care	Hospitals and Acute Health	33	416
PFI Extra-Care Sheltered Housing (Mary Seacole)	Department of Health and Social Care	Social Care	25	3,5

to the private sector. PFI projects also encourage innovation, good design, and delivery of high quality and productivity. PFI can decrease costs and provide a better quality result. It allows doing things that are difficult such as stimulating a new private sector industry development. It also encourages the delivery of projects on time because the private sector cannot receive payment until they deliver the asset. Additionally, PFI affects performance by providing better services determining service levels and imposing penalties in the case of nondelivery of an asset. The public and private sectors make standardized contracts in PFI projects, and both parties encounter fewer contractual errors (National Audit Office (NAO) 2011).

On the other hand, PFIs have some potential disadvantages too. One of the important disadvantages is that PFI can decrease competition because small and medium-sized enterprises may not afford to bid for projects due to their high costs and complexity (House of Commons Treasury Committee 2011). Furthermore, the

lack of long-term contract flexibility can be a major problem for the private sector; therefore, it is very important that both parties negotiate (Dixon et al. 2005). Besides, in PFI contracts such as with a duration of 30 years or more, contracting parties have limited aptitude to predict, prove, or write unexpected events in the future. The complex nature of these contracts includes many parties that have different benefits may be an additional reason for asymmetric information (Mansor and Rashid 2016). Lastly, the public sector pays for the risk transfer in PFI contracts, but the ultimate risk still belongs to the public sector, and also PFI may heighten commercial risks due to expensive contracts with long periods (NAO 2011).

Summary

PFI is the financing of public projects through the use of the private sector. Initially launched in 1992 in the UK, but it has been increasingly used in

many countries nowadays as part of financialization and privatization programs. It uses the private sector's management skills and increases efficiency. The main purpose of PFI projects is to increase the collaboration between the private and the public sectors.

Product Life Cycle

José Satsumi López Morales
Economic Administrative Department,
Tecnológico Nacional de México/IT de Veracruz,
Veracruz, Mexico

Synonyms

Commercial life; Life cycle; Portfolio of products;
Product management; Useful life

Definition

Product life cycle is a model that explains the route of a certain product through its useful life in an industry. This model divides the life of a product in four stages; these stages constitute the life span of a product. The first stage is the introduction, where the product is designed, manufactured, and released to the market. The second stage is growth, where sales increase due to increased market penetration and product improvements. The third stage is maturity where sales reach its peak and the cost of the product is reduced by scalability. The fourth stage is the decline; at this stage sales begin to fall probably due to the introduction of new products or obsolescence (Maqbool Waris et al. 2016; Levitt 1965).

Introduction

As stated in the definition, the Product Life Cycle (PLC) is a way of explaining the passage of a

product by an industry. Everyday companies of all sizes and sectors launch new products into the market. The main objective is that the product is as long as possible in the market in order to obtain profits; however, it cannot be used forever, each product has a time of useful life. In this order of ideas, Vernon (1966) proposes the model of the PLC that works to explain the transit of the products through the market where they are offered.

As mentioned, PLC consists mainly of four stages (introduction, growth, maturity, and decline) (Fig. 1). PLC allows the explanation of the dynamics of the markets in relation to the products that are offered (Day 1981). Additionally, PLC was developed from an analogy of biology, specifically from the stages of human growth (Todd et al. 1980). In this order of ideas PLC is a tool for companies to formulate strategies that fit each stage of the PLC.

Originally, PLC was conceived to explain the decisions of foreign direct investment of the companies (Audretsch et al. 2017; Vernon 1966). But in the course of time it became a tool widely used for marketing (Kotler 1984), and among others, it has the purpose of increasing the profits of the products, reduce costs, maximize the value of the products offered and generate more value for customers in the product offerings (Stark 2015).

Also, PLC specifically explains why a product is released. It is important to mention that PLC is not the same for all products; there are products whose life cycle is much shorter than others or products that remain long in the same stage. The above leads to making better decisions about products.

Key Issues

First of all it is important to define what the product is, which in its simplest conception is a set of benefits that a company offers to its clients (Kotler 1984). Few management concepts have been so widely accepted, but at the same time reviled as PLC. The key issues of this concept focus on its simplicity and focus. Some authors point out that PLC has the disadvantage of being very simple (Lambkin and Day 1989), on the opposite side are

Product Life Cycle, Fig. 1 Product life cycle (PLC)

those that consider it a tool of decision making on the strategies of Business (Anderson and Zeithmal 1984). For the above in both cases it is advisable to establish an analysis.

As mentioned, PLC consists mainly of four stages (introduction, growth, maturity, and decline). However, it is important to mention that in each stage the decisions about the products are different. For example in the introductory stage the uncertainty is greater, in order to reduce it the companies manufacture different variants of products (Klepper 1996).

Table 1 presents the characteristics of the stages of PLC. The characteristics presented give an overview of the behavior of the products according to the stage where they are. It is important to mention that these characteristics can have variations according to various factors such as the strategy of the company, the response of the clients, the type of product, and the seasonality. Also, as mentioned, the same product can have different life cycles mainly by the market where it is.

It is important to answer the question that at the time of the PLC the product starts to generate profits. First, during the introductory stage it is lost, since being a new product in the market it still does not present a high volume of sales. It is from the growth stage that the product begins to generate enough sales to obtain profits that allow the recovery of the investment. In the maturity stage the product reaches its maximum peak of sales

and profits, at this point of the PLC it is possible to start considering innovations in the product in order to lengthen the life cycle and/or to think about entering international markets.

One of the most important criticisms of PLC is its simplicity (Taylor 1986). This is based on the fact that the model in its original conception has not considered several exogenous factors that can affect a product, such as: location, environment, and social conditions of the environment. And despite the above, PLC is a very useful strategic analysis tool.

Also, for a company, the development and production of a product is less complex (Stark 2015). The critical part lies in the control of the PLC, since the loss of control at some stage of the PLC can cause significant losses. For example, production costs can be exceeded and/or late on the market causing damage to the company's customers.

One of the main defects of the PLC is the way they are approached by the model innovations (Taylor 1986). In this order of ideas, the products are released to the market (introductory stage) when they are recently created, in most cases these products come to replace others who are in another stage of PLC. Generally, the new products and the products they replace it with are very similar; this generates duplicity. Therefore, innovations within PLC are difficult to address sometimes.

Product Life Cycle, Table 1 Stages of PLC

Characteristics	Introduction	Growth	Mature	Slope
Sales	Low sales	Rapid increase in sales	Maximum sales	Low sales
Costs	High cost for customers	Average cost per client	Low cost per client	Low cost per client
Utilities	Negatives	Increase in profits	High utilities	Low in profits
Clients	Innovators	Early adapters	Majority average	Lingerer
Clients	Few	Growing number	Stable number that begins to shrink	Dwindling number

Source: Kotler and Armstrong (2008)

Another important factor to consider in the PLC is the sustainability. Nowadays companies have to look for alternatives of how to optimize their resources through the technology to be able to offer products friendlier with the environment. Through collaboration with other companies, it is possible to minimize the negative effects of some products with the environment (Trujillo-Suarez 2015; Vila et al. 2015). Also its approach is diverse. Initially it was conceived to explain the investment decisions of the Companies (Vernon 1966). Later, because of its simplicity, it has been used to explain the behavior of business (Audretsch et al. 2017; Anderson and Zeithmal 1984) and to make marketing decisions (Borna and Wahlers 2018). Within the PLC, it has been identified that the same product can be in two stages of the PLC. This refers mainly to products that have been sold in different markets at the same time as companies have used different strategies. For example, in developed countries, mainly products are exported in the introductory stage and in emerging markets, mature products are exported (Audretsch et al. 2017).

It is important to mention that PLC was taken as an analogy of biology; however, one of its limitations is that some products do not behave like a living being (Borna and Wahlers 2018), i.e., it is not generalizable to all. There are products that skip stages and others are kept many years in the same stage, such as Coca-Cola. This makes the PLC not a suitable tool for decision making in certain products.

In conclusion, PLC is a model that caused great impact in its launch; however, it has been surpassed by other models that serve to analyze the markets

and products that exist in the market. Despite this, PLC continues to be a benchmark for analyzing and making decisions in various fields of management, business, and engineering (Goncalvez de Oliveira 2018; Stark 2015). In addition to the increasingly sophisticated product offerings, the increase in competition and the speed of the markets makes it necessary to be more dynamic in the PLC.

Future Directions

The main challenge of PLC is to continue being current today. This validity goes beyond continuing with its initial proposals; it lies in updating the current business needs. Also, following this trend as future areas of research is to test the effect of sustainability in the PLC. Also, to determine new factors that affect the extension of the PLC, in turn to serve as a strategy for companies. While PLC is applicable to several areas of knowledge, it is important to expand its application to other areas. It is important to generate metrics of each of the stages of the PLC to ascertain if you can maintain more or to extend PLC. Likewise is important to test the issues and challenges for the management of a product that have different stages of PLC in different markets.

Due to its importance in the economy, the application of PLC in the service sector is an important area of researching for extending the knowledge about PLC. PLC has shown to be useful for taking decisions about the management of products. However, it is important to clarify if PLC can explain the useful life of services or hybrid products (a mixture between products and services).

Summary

The PLC model is a way to explain and understand the passage of a specific product for a market. The main objective of PLC is to enlarge the life of a product in order to obtain more economic benefits for the organizations. For its implementation, PLC is divided into four stages that depicts a life cycle; these are: introduction, growth, maturity, and decline. Its importance is centered in the time that a product can offer benefits to its consumers and which are the best and suitable strategies to carry out for a specific product. Also, the products have different stages depending on sales, costs, utilities, and clients.

For around 50 years, the PLC has been the most used mode to explain the behavior of a product in a market; however, some new advances and ways to explain the life span of products have relegated it. Is very necessary to update PLC by connecting it to new business practices and approaches (i.e., organizational learning and technology). Furthermore, PLC have been enclosed only in products but in current times the services are an important part of products (for example, the delivery services when you buy a product online); for this reason it is necessary to develop a model of PLC with included services.

Product RED

Gizem Aras Beger

Faculty of Business, Department of Business
Administration, Yasar University, Izmir, Turkey

Synonyms

RED; (RED); Product (RED); (PRODUCT)^{RED};
PRODUCT^(RED); (RED)TM; (Product)^{REDTM}

Definition

Product (RED) is a private-sector consumer marketing initiative that was launched formally by singer Bono and Bobby Shiver, Chairman of DATA at the World Economic Forum Annual Meeting in the Swiss mountain village of Davos in 2006. Product (RED) is designed to raise funds and create awareness for the Global Fund to fight against AIDS, Tuberculosis, and Malaria in Africa. As a brand licensed to companies, (RED) teams up with the world's well-known brands or companies. Each brand or company produces unique (RED)-branded products or services and donates money from their sales to support the Global Fund. So far, Global Fund grants supported by (RED) have benefitted millions of people's lives in Africa through a diverse range of life-saving programs. As a celebrity-driven charity, (RED) has received support from numerous influential celebrities, including singers, musicians, actors/actresses, models and founders. They help energize people who want to participate by creating an interest in the brand. These aid celebrities or brands mainly create motivation for action via the digital dissemination of ideas, meanings and messages through a network of channels to the wider community. (RED) successfully creates a sense of unity that brings together business people, celebrities and consumer-citizens around international aid. In doing so, (RED) offers a more innovative and sustainable approach to funding to fight AIDS thanks to

multi-stakeholder and multi-sectoral collaborations between business and public.

(RED): An Explanation of its Relationship with ONE

Product (RED), styled as (PRODUCT)REDTM, is a licensed brand (Ghosh & Shankar, 2013) that combines business and international aid to raise awareness and funds to help eliminate AIDS, tuberculosis, and malaria in Africa (Bell, 2011).

(RED) was initiated in 2006 by Bono and Bobby Shiver (Phelps, 2017; Ponte et al., 2009) as a business funding model for philanthropic efforts (Wirgau et al., 2010).

(RED) is also a division of the ONE campaign, "a global grassroots advocacy and campaigning organization" that aims to eliminate extreme poverty and treatable disease (ONE, 2019; RED, 2019a). (RED) is recognized as a tax-exempt and charitable organization by the UK Internal Revenue Service under Sect. 501(c)3 (RED, 2019f).

(RED) Logo

The (RED) logo, developed by Wolff Olins, facilitates the transition of (RED) from an idea to a tangible, visceral vision. There are many versions for each company and their products (Wolf Olins, 2019), such as The Gap^(RED)'s best-selling T-shirt, INSPI(RED).

The (RED) logo is a strong visual symbol that represents all partner companies with the same vision. Therefore, it provides a co-branding umbrella model that unites global activism around a shared concern for people suffering from HIV/AIDS in Africa (Duvall & Guschwan, 2013; Ponte & Richey, 2014).

(RED) Manifesto and Consumers

The (RED) manifesto has an explicit mission to eliminate the spread of mother-to-child HIV transmission and to encourage consumers to buy (RED) products to support the Global Fund

(Gallant, 2013). The (RED) manifesto provides consumers with a clear sense of mission: “Every Generation is known for something. Let’s be the one to deliver an AIDS-free generation” (Phelps, 2017). Consumers seem to have responded positively to Product (RED) by buying (RED) products, such as iPods, T-shirts, watches and cologne (Wirgau et al., 2010). Since its launch in 2006, (RED) says it has generated over \$600 million and impacted the lives of over 140 million people through HIV/AIDS prevention and treatment services in Ghana, Kenya, Lesotho, Rwanda, South Africa, Eswatini, Tanzania and Zambia (RED, 2019b).

(RED) Partnerships

(RED) is a co-branding exercise of individually-negotiated licensing agreements with many well-known companies, such as Apple, MCM, Starbucks, Durex, Belvedere Vodka, SAP and Air Asia (Peterson, 2009; RED, 2019e). (RED) also develops collaborations with diverse brands operating in distinct sectors, such as HBO, Youtube, RollingStone, and 5B, which support (RED) activities in many ways (RED, 2019e). For instance, “*The Lazarus Effect*” documentary, which emphasizes the impact of antiretroviral treatment for HIV/AIDS patients by transforming their lives from debilitating to a healthier, productive life, was produced in 2010 through collaboration between HBO and (RED). Similarly, the (RED)Nights concert series organized by Rolling Stone Magazine in 2009, donated a proportion of the ticket sales to the Global Fund to Fight AIDS (Kreps, 2009).

The PRODUCT (RED) campaign brings companies together to communicate with consumers through diverse (RED)-branded products and services (Peterson, 2009) to make their purchases meaningful (Dadush, 2009). These companies donate a portion of the profits from these sales to a nonprofit agency called the Global Fund (Bell, 2011; Peterson, 2009). This then distributes money in six African countries to fight AIDS (Bell, 2011). For instance, through the sale of (RED) products (iPhone/iPod/apple watch

devices), Apple has raised over \$200 million for the Global Fund (RED, 2019c). Similarly, Starbucks has generated \$15 million through an in-store promotion in its American and Canadian outlets (RED, 2019d).

Celebrity Involvement

One of the most common and successful strategies used by (RED) has been celebrity involvement backed by the world’s most iconic brands (Mitchell, 2016; Ponte & Richey, 2011; Richey & Ponte, 2008). It heavily employs celebrity activism and ethical consumerism, mobilized by aid celebrities through a kind of affective affinity that helps to move attention from the product to a social cause to help distant others (Ponte & Richey, 2011). From the very beginning of the (RED) story, Bono and Bobby Shriver have themselves paved the way for this transformation from a personal to a global commitment in fighting AIDS/HIV (Dadush, 2009).

In this way, (RED) can strengthen its meaning, power and impact through the many celebrities behind it, including Oprah Winfrey, director Steven Spielberg, model Gisele Bundchen, actress Scarlett Johansson and photographer Annie Leibovitz (Arnoldy, 2007). Such (RED) celebrities embody “a discourse of race, consumption, philanthropy, and ultimately of globalization” (Bell, 2011). Through working with these celebrities, (RED) has attracted much attention and raised awareness about the fight against HIV/AIDS (Farrell, 2012; Ponte & Richey, 2011).

Summary

(RED) has clearly pioneered a new mechanism based on co-branding and consumption in the fight against disease and poverty. It has succeeded in engaging business and capturing consumer attention by using various effective communication channels that help to transmit the (RED) mission of an AIDS-free world to a wider community.

Both as a new way of fundraising and as a means of CSR, (RED) represents a new and

much more comprehensive approach to doing business (Dadush, 2009; The Global Fund, 2010). Its success seems likely to push other firms to generate (RED)-like value for society.

Synonyms

[Cyclical economy business models](#); [Service-focused product outcomes](#); [Servitization](#); [Sharing economy business models](#)

Definition

The overall objectives behind *product-service systems* appear threefold: (1) endeavoring to

design and create a seamless integration of product and service in patterns of consumption (Especially where aimed at consumer-end practice; partially yet significantly, to influence consumer habits); (2) doing so by sustainable means and to sustainable ends (e.g., (i) achieving waste reduction and energy savings; (ii) maintaining businesses' market position; and (iii) doing so with social responsibility in mind, esp. with regard to the management and reuse of finite resources); and (3) engaging consumers and customers (as well as other stakeholders) in the co-design of product-service delivery. The shift from product purchase and ownership to utility, use, reuse, sharing, pooling, etc. had characterized product-service systems (Without capitalization hereinafter) to date. The conceptualization and design of product-service systems are aimed at seamless integration at each stage and value component of creation, customization delivery, use, consumption, and exchange. However, this is not without challenges innate to a number of strategic (For example, Leseure et al. (2010) examine servitization challenges for manufacturing firms), economic, technological, operational, and cultural characteristics that businesses, partners, regulators, consumers, and users need to contend with. As the coined term indicates, there are sets of hybrid, complementary, and somewhat ambiguous qualities at the heart of the meaning of "product-service systems" (PSSs). An integration – primarily within a business model (product-service systems may exist outside of *business as such*). However, with increased privatization and commercialization of the public sphere, it is safe to describe the term with due attention to "business models") – of the [traditionally; ostensibly] tangible products and manifestly intangible services (though services often consist of some key material activities). Arguably, the notions of intransience vs transitory nature distinguish the two. What is important to note here are the shifts from production to provision and the emphasis on function and utility. Components may include networks, chains, operations, and infrastructures both extant and bespoke. Song (2017) summarizes (Derived from Becker et al. (2008)) a product-service system as an

“integrated bundle of product, software, and service elements.”

Introduction and Developmental Overview

Such combinations as described above have become very pronounced since the practice was first employed in the 1990s; e.g., Vandermerwe (2000) refers to an early, healthcare-related case from 1997, even before the then novel term was fully formulated. (First authoritative definitions and fully articulate use traceable to early authors such as Mont (2000, 2002).) Moreover, arguably, there were elements of service added to products developed and marketed by leading firms throughout the history of mass production and product-oriented markets (e.g., prominently, Shapiro and Mathe 1993).

However, there are three considerable aspects to product-service systems that set them aside from any such past examples. First, are the technological conditions that enable a true integration of tangible and intangible of the incidences of production of a unit of value, and the continuation of services accompanying such integration. These conditions become ever more pronounced with the advances of interactive digital technologies and increasingly hybrid intangible interrelationships of products and services. (Brands that may spring to mind include Uber, Kapten, and Lyft in automotive mobility and Microsoft, Apple, and others in IT.) Second, product-service systems are also linked to economic tightening and the intensifying competition in many markets characterized by growth through integration and consolidation. (See below on key developments in autonomous vehicles and PSS collaborations and projects related to them.) (e.g., Smirnov et al. (2017) speak of commoditization and market saturation forcing companies to implement new product and marketing paradigms, frequently formulated as orientation to services relating to PSS life cycles.)

The third, and for this definition the most vital aspect – involves the social, environmental, and economic responsibilities of businesses ranging

from small manufacturers, design studios, to start-ups to multinational corporations. Most notably among the latter two, vertically integrated (loosely, at times) *co-opetition* networks (e.g., Ritala et al. 2014) tend to be crossing industries which are epitomized by the meaning of PSS in the context of sustainability. (Examples also include entrepreneurial product design firms (For example, assastudio.com for cutting-edge practice of co-design and PSS in product design, 3D printing, and innovation) engaged in 3D/4D printing for varied corporate and institutional clients). Thus, product-service systems are often seen as green and environmentally friendly, resource-fitting, and socially responsible (e.g., sharing by pooling of reusable products, services, and resources) and attaining new forms of improved value-for-money on multiple levels, from users/consumers to businesses and (supra)societal-level clienteles (e.g., the increasing consideration of blockchain as such a tool. (See the World Economic Forum sources, by Liao & Fang (2020), and May (2020) for further details on a qualitative shift, adopting this novel tool globally).) This indeed often consequently proves a value proposition fit for marketing purposes at a time when many stakeholders (from consumers to high-end regulators) espouse socially dependable discourses.

This overview of the term *PSS(s)* shall aim to elucidate on the features referred to above. This, especially as commonsensical manifestations of the specialist term and its everyday connotations continue to gain significance in everyday use (e.g., car-pooling, pay-per-use); in public discourse, the media, and commerce, as well as in academic treatises and reference works. Notwithstanding express environmental value, the relationship of PSSs with the somewhat problematical (Problematical, as it was indicating a largely unfounded optimism of the late 1990s of boundless growth of developed economies and the postmodern *belief* that consumption would continue unabated and extrapolated into a future where economic woes of the past would no longer happen to occur in post-industrial societies. Returning to basics appeared a shock in the post-subprime crash world, and matters of tangible production,

utilization, and control over resources; “real,” tangible value; and such like had once more become very prominent) phrase “experience economy” lay at its consumer-oriented aspect at competitive-market base. It is also worth evaluating the delivery on promises of social, economic, and environmental sustainability. This particularly applies in the context of growing corporate consolidation, thus far metaphorically exponential in its nature and level; yet it is conceivable that such exponentiality of use may actually materialise in its nature and level. Here is where some of the most widely reported contemporary examples in product-service systems appear to occur (including the acquisition of innovations). For example, driverless cars and other autonomous vehicles (AVs) with their environmentally friendly features. At the turn of the decade, these initiatives are being matured by the world’s foremost ICT service-led firms such as Amazon and Google (e.g., McFarland 2019; Hearn 2019), while prior leaders in the automotive industry and early AV innovators (For more on innovation and PSS, see Velamuri et al. (2013)) may repeatedly take second place (Lauer 2019) as understood in examples and analyses cited. Originally, these have been expanding by start-ups and automotive firms. (PSS in automobile markets appear at times in “micro”-factory contexts: e.g., eco-friendly automobile retail, as covered by Nieuwenhuis (2018), preceded by a different take on a related subject by Williams (2006).) This occurred outside the realm of major [digital] technology (hardware, software, internet) corporations. The latter have shown considerable interest in the latter part of the twenty-first century’s second decade, with a likely future impact. The subsector is significantly defined by a set of start-ups or ICT technology-driven mobility service firms including Uber and Lyft, Nvidia, and Mobileye suppliers of vision-based AVs and car navigation software. The emergent subsector is currently particularly of interest to Apple’s autonomous driving systems and to Google – with its expansive ambition – while analysts such as Keith and McDuffie (2020) suggest that integration of such service approaches and established automotive firms is where the solution may be. In order to understand the roots of such fairly advanced occurrences, it is essential to

look at the development of the PSS concept and its fundamentals.

Mont (2000, 2002) is among the very first authors (For an early definition of PSS, see also Roy (2000)) who articulated PSSs as a novel entity in its own right. Indeed, her 2002 paper is so instrumental in defining the nature, scope, and impact of PSSs – in its infancy at the time – that it deserves special attention. This entry refines the terminology and advocates the then budding PSSs for widespread adoption, decrying the absence of policy support and of adequate operational infrastructure at the time. (Such infrastructures are fast emerging as will be seen below, with some considerable integrative ICT leaps in the late “twenty-teens.”) Mont maps out the development of the PSS approach and scant extant analysis of the time, further articulating the need, means, possible and likely design characteristics, and directions for PSS(s). Advocating for the *dematerialization of the economy* and creating the products and services with unbound performance though with a lower material flow to unburden the environment, Mont stated that conditions were ripe for such change. Namely, 70% of developed economy workforce was already in services and that 65–75% of those employed in production engaged in service tasks including research, process design, logistics, planning, as well as legal, HR, and accounting (2002: 238). Hence, the author’s summative proposal is thus: to develop PSS by means of (1) shifting the emphasis from product sales to product use and (2) the change to a “leasing society.” Citing another seminal work by Stahel (1997), Mont emphasized the *functional economy* attribute of services; before *cyclical economy* itself was formulated, Mont precludes it with the insistence on “closing the material cycle” and the stress on the *consumer end part product life cycle* in a cultural shift toward *provision*: the utility approach that replaces the product focus of traditional modes of consumption.

Mont (2002) thus defines a PSS:

as a system of products, services, supporting networks and infrastructure that is designed to be: competitive, satisfy customer needs and have a lower environmental impact than traditional business models.

Many practical challenges to implementation are cited in the text, including sub-optimization which stands in the way of integrating the elements of PSSs into systems with reduced environmental impact. As product-service systems developed over time, these were overcome by organizational means chiefly employing digital technologies covered in the latter part of this entry.

An equally influential contribution by Tukker (2004) presents a classification of PSSs, citing eight product-service system categories under three main principal headings, as shown below. (See also Van Ostaeyen et al. (2013).)

Product-oriented services:

- *Product-related service*
- *Advice and consultancy*

Use-oriented services

- *Product lease*
- *Product renting or sharing*
- *Product pooling*

Result-oriented services

- *Activity management/outsourcing*

- *Pay-per-service unit*
- *Functional result*

(Tukker 2004: 248–9)

Regarding the visible applications of PSS in everyday use, many noteworthy examples include Rolls-Royce aviation engines and parts, not sold but leased by means of “Total Care” and “power by the hour” service programs (Isaksson et al. 2009), or the strategic move by Philips from focusing on the long-life induction lamp (Stahel 1997: 127) to “pay-per-lux” program (Philips 2013), a form of *pay-per-use* PSS (e.g., Tauqeer and Bang 2018; Tukker 2004; Maaruf and Mohamed Abdi 2017). In media and entertainment sectors, the crisis brought about by the late-1990s Web and its propensity for copyright theft had led to the development of many service-oriented usage models under the overall heading of *streaming*. The utilization of product (music, film, TV, gaming, etc.) and service (streaming, smart search, bundling, mobile apps) had led to developments that far surpass original expectations of contingency tactics in the early 2000s. Such contingency tactics, including – in terms of content-consumer targeting and licensing models (on licensing, see Dutra et al. 2018) – Netflix or Spotify media and rather notably, a

Product-Service Systems, Tukker’s (2004) classification of main categories of product-service systems. Tukker, A. (2004). Eight types of product-service system: eight

ways to sustainability? Experiences from SusProNet. Business strategy and the environment, 13(4), 246–260.

highly competitive market for *smart speakers and virtual assistants* (e.g., Chung et al. 2017). On virtual assistants, both pragmatic and ethical considerations arise in healthcare (e.g., Hoy 2018). This and other related contexts are considered in the section below.

Potential Future Developments and Noteworthy Considerations

Repeated references are being made to healthcare reform driven by artificial intelligence/AI (e.g., Jiang et al. 2017; Baskaran et al. 2010). It is not inconceivable that a near foreseeable future may be characterized by a blend of health services delivered by machines, *bots*, and humans alike through seamless PSSs further defined by increased automation. Indeed, a working paper dated 2019 hails such prospects through a technological methodology system far surpassing original expectations (part of a thorough speculative investigation by Limata 2019). Given past practice in utilization of PSSs for healthcare (e.g., Mittermeyer et al. 2011) and some notable extrapolations of AI-blockchain combinations for PSS such as Limata's 2019 postulation, there appears a substantial convergence potential in the field – and not only confined to the impact of such hybrids in healthcare. Expanding on further, with examples of digital information management is *the notion of Blockchain [4.0]*. Blockchain crypto-technology forms a means of transparently storing all transactional information on to public, decentralized networks no single user may control. Such information forms a *block and its sequential use manifests as a chain*. In the context of *circular economy*, Limata (Constituent works of Limata's speculative inquiry deserve scrupulous attention surpassing this definition) (2019) *draws on the work of multiple authors* and postulates probable outcomes of the *r/evolutionary* potential of blockchain, as its constituent technologies may be implemented in a new social, political, and economic paradigm as they emerge from relative obscurity. Its meta-technology permanently stores data immutable by any one user, on all transactions and communications, be it

monetary (“Blockchain 1.0”), *legal* (2.0), *social* (“3.0”: deserving more attention), or “Blockchain 4.0.” The latter concerns likely integration of AI and blockchain's autonomous *smart ledger*. This may potentially change the way all human activity is recorded, registered, distributed, managed, legislated, monitored, accounted for, paid for, and controlled. Relationships of trust and enforceable records normally mediated by institutions across various sectors, professions, and (supra)state organizations would be delegated to an un-meditated network of computers and cryptic itemized units of software content capable of memorizing every activity in a dynamic way. Its *general-purpose* technology would thus form an *organizing paradigm* affecting all areas of *community life* (3.0), *law* (2.0), and *commerce* (1.0) through a *public, private, or consortium blockchain*. Community life may further consequently extend to encompass *government/elections, science, health, and culture* and *even the realm of ideas*. Conceptually expanding PSS, solutions offered by blockchain authors and practitioners appear to nest PSS within infinite transparency of all activity based on network integrity (*intrinsic trust*), peer-to-peer distributed power (*no one dominates*), value incentives (*all stakeholders*), security (*no repudiation*), privacy (*people control own data*), preserved/enforced ownership/rights, and inclusion (low barriers). PSS goals – seamless integration and elegant design for a circular economy – may thus be enabled by such technology, which does rest on global consensus. It remains unclear how probable such consensus may be and whether the general-purpose technology of such reach and richness may be adopted as broadly as projected.

Summary

Product-service systems are growing in relevance and ubiquity; many of the day-to-day consumer preferences have been marked by product-service systems' impact. The very notion of a product-service system (PSS) relates to more than one aspect of sustainability. These include environmentally friendly practices, business models for

the cyclical economy, resource-sharing, and others. It is most likely that PSSs will become more prominent in the future. They are intrinsically connected to some key features of the state-of-the-art technologies defined and supported by computing, including but not limited to the Internet of Things and blockchain.

Definition/Description

The idea of professional ethics is built on the twin concepts of profession and ethics. Profession is any work involving superior skills based on specialized knowledge and training. Ethics is the basis for understanding what is right and wrong.

Applying the idea of right and wrong to the conduct of a profession rests on professional ethics. In simpler words, practicing a profession in such a manner that the practitioner has an innate sense of right and wrong is following the professional ethics of any type of work. Professional ethics is concerned with the ethical issues and challenges related to professions such as medicine and law. The professional ethics are in the form of principles, guidelines, and rules. The members of the profession are organized in the form of a body or association. Such a body creates and adopts a professional code of ethics for its members who commit themselves to follow it in the practice of their profession. The codes of ethics are formulated as there is asymmetry of power between the professionals who are educated, trained, and specialized in a field of activity and the clients who demand services from the professionals but are not aware of the details of the field of activity. The clients just rely on the professionals in good faith. Formal declaration of code of ethics serves to provide assurance to the clients that they will not be put to disadvantage.

Introduction

Ethics (also called moral philosophy) is a branch of philosophy that deals with the questions of what is right and wrong, moral and immoral, or good and evil. Profession is an occupation that requires special knowledge and skills through study and training such as engineering, law, or medicine.

Applied ethics, using the moral philosophy, provides guiding principles that help to decide the standard of behavior expected of a person or a group in a given situation. Professional ethics are a subset of such guiding principles that apply to a certain profession and are intended to help the experts who possess specific knowledge and skills, certification, and perform the duties of a particular profession.

Professionals adopting a particular profession get together, usually in the form of an association and federation, to evolve a set of principles that they agree to apply to themselves in the conduct of

their occupation. Such a set of principles is called the professional code of ethics.

The popular example of professional code of ethics is the Hippocratic Oath that is administered to graduating medical students all over the world. It is an ancient Greek oath that is adapted to suit the modern times and that commits the medical professionals to several duties such as treating the sick to the best of their ability, preserving the privacy of their patients, and passing on the medical knowledge to the next generation.

Profession, Professional, and Professionalism

The world of work occupies a major part of an individual's life. Work is essential to living and existence. During the course of work, individuals adopt certain occupations based on the particular skills that they have inherited or learned or both. Occupation is a general term to denote any work that an individual is engaged to earn livelihood. The emphasis in occupation is on what one does to earn livelihood. Examples of occupation are acting, community work, photography, stock broking, and web designing. When the work is primarily manual and mechanical involving dexterity in working with hands and machines in which case it becomes a trade. Example of a practitioner engaged in trade is beautician, carpenter, and waiter. Work involving higher level skills backed by specialized knowledge and training is a profession. Examples of a profession are medical doctor, mining engineer, lawyer, and teacher.

A professional is a person who belongs to a profession. An occupation transforms to a profession when there are certain characteristics present. The professionals get together in a formal arrangement such as an association to give themselves a charter of duties and responsibilities and adopt self-imposed norms of conduct in their profession. They give themselves to moral commitments and they assure their clients and customers that they would adhere to the norms. The professionals see themselves as a part of fraternity that professes

common values. They usually adopt a voluntary code of ethics.

Professionalism is the conduct exhibited by and the qualities and attributes that characterize a professional. Contrary to common perception, professionalism is not merely personal competence but more. Some of the major attributes that distinguish a professional are specialized knowledge in the professional area, competency to handle the job, commitment to the profession, and self-regulation of behavior and conduct in performance of duties. Professionalism is a trait that is much valued in organizations as it brings a lot of benefits.

Ethics, Applied Ethics, and Professional Ethics

Ethics is a term derived from Greek *ethikos* that is itself derived from *ethos* which means custom, character, or habit. Ethics is a branch of philosophy, called moral philosophy that is concerned with defining and developing the concepts of right and wrong behavior. These concepts are immutable; they do not change and are not relative to the situation or circumstances.

Ethical theories are generally divided into three types: meta-ethics, normative ethics, and applied ethics. Meta-ethics deal with the nature of moral judgment whether it is absolute or derived. Normative ethics is concerned with the criteria that define what is right or wrong. Applied ethics relates to practical considerations involving morality and applications of concepts of ethics to various spheres of life and professions such as medical ethics or business ethics.

Professional ethics deals with the ethical issues and challenges related to certain professions. It provides the means to resolve ethical problems. The professional ethics usually are in the form of principles, guidelines, and rules. Often, the professionals as members, in the form of association or bodies, adopt such principles as guidelines as they go about practicing their profession. These principles help them to resolve ethical dilemmas that they might face in the course of performing their duties and responsibilities.

Professional Code of Ethics

Professional code of ethics (or sometimes, professional code of conduct) are based on the principles of professional ethics to propose and prescribe the required norms of behavior for members of a particular profession. Such codes need to go beyond the law to be effective. A code of ethics is about choice; if there is no choice, then it is not ethics but law. The code of ethics encapsulates the expectations that society including stakeholders, such as clients, have of the professionals.

The reason why professionals are expected to have voluntary, self-imposed codes of ethics lies in the concept of “power gradient.” Power gradient is the difference that exists in power held by a superior in comparison to the subordinate. The steeper is the power gradient, the more power the higher authority has comparatively. The concept of power gradient can be applied to the situation of a professional like a doctor or lawyer and her relationship to her client. Almost always, the professional is expected to have more knowledge, information, and expertise than the client. In fact, the client pays for the expert advice of the professional.

The professional has an asymmetrical position with respect to her client. To compensate for the unfair balance of power in the professional–client relationship, there need to be assurance from the professional that the expertise will be used for the benefit of the client rather than to the advantage of the professional. Further, assertion is also needed that the expertise will not be against the client for monetary or other benefit. In simple words, the doctor or the lawyer should not charge a very high fee for services that are not truly valued at that price just because the client cannot bargain the price. The professional should not provide inferior service charging a fee that the client pays for superior quality of service. Overall, the power gradient concept entails that the professional should ensure that the client is not made to suffer on account of asymmetry.

The professional code of ethics may not have the legal sanction behind it to be enforced. In some cases such as medical councils, there might be some formal power of registration or

certification that might be invoked to enforce the code of ethics. There might be penalties if any of the codes is not followed. These penalties might be deregistration of the certification that may make it impossible for the professional to carry on practicing her profession. In most other cases, there is no legal sanction behind the professional code of ethics. There is just the sanctity of the collective strength of the body of professionals that creates the code and expects it to be adhered to. Thus, in most cases there is only the soft power of the weight of the collective body behind the code of ethics and the respect that such an association of professionals commands. The existence of a professional body that creates code of ethics for its members helps to raise the status of the profession too if it is made public and is open and transparent. However, there could still be a risk of window dressing if the code of ethics is made public.

The influence of professional code of ethics often goes beyond the profession itself and also beyond national boundaries. An example is the case of medical ethics where the code of ethics may have a salutary effect on other professions. Besides, a national voluntary code may have ramifications beyond the borders like the medical ethics codes having relation to the International Code of Medical Ethics of the World Medical Association.

Emerging Professions and Code of Ethics

Traditionally there were three professions to which the code of ethics was applied. These were the divinity, law, and medicine. Later the military services were added. Over time, new professions have emerged that have required the development of the professionalism and consequently the code of ethics for these new professions. Teachers, librarians, managers, accountants, auditors, and drug testers are some examples of such professions. All of such examples are of professions where people place faith in the experts and rely on what they certify or suggest. There are also emerging professions such as artificial intelligence experts, big data specialists,

genome scientists, and bioinformatics experts. These are some such new careers opening up. Some of these careers already have ethical dilemma and issues to resolve. Genetic testing has been a controversial area where several ethical dilemmas are faced. There is the issue of genetic testing results being shared with insurance companies, employers, and others endangering the safety and infringing the privacy of individuals. There is also the issue of conflict of interests among the individual rights as well as the demands of public health. Another interesting example is of the emerging ethical dilemma in the area of commercialization of space including the lunar development and outer space commerce.

Sustainability and allied issues are opening up several avenues of new professions, careers, and jobs. A few examples of such professions are carbon management consultants, renewable energy specialists, waste management specialists, energy efficiency specialists, and environmental law experts. It is to be noted that in each of these professions assurance is required from those entrusted with responsibility of managing the physical environment.

Over time, it is expected that as the existing established professions fine tune their codes of ethics in light of new developments, the emerging and newer professions would have to evolve their codes of ethics in line with the demands of the situation.

Summary

A profession is work involving higher level skills backed by specialized knowledge and training. Ethics is branch of philosophy dealing with right and wrong behavior. Professional ethics is concerned with the ethical issues and challenges related to certain professions. It provides the means to resolve ethical problems. Such professional ethics usually are in the form of principles, guidelines, and rules.

Professional codes of ethics are often voluntary statements about how organizations and individuals will behave with members within and outside. As such, the codes of ethics spell out some of

the more obvious and important ethical values for a professional organizations and professionals to follow. Ethical behavior requires that the people involved in the profession have to articulate their ethical values. Creating and accepting a code of ethics helps the professional organizations and the professionals to determine their ethical values and to codify them in a set of principles that can form the guidelines for their behavior.

Existing professions develop their codes of ethics and continue to update and refine them in the light of changing circumstances. Newer and emerging professions evolve to absorb the challenges that confront them and come up with codes of ethics that would suit their requirements.

Definition/Description

Public participation is an accessible, responsible process through which individuals and groups

within a typical geographical area exchange views and influence the decision-making process (Odhiambo and Opiyo 2017). Similarly, it can be viewed as a public-based process that allows the goals and needs of the populace to be structured at the community level, and also one in which the populace work with governmental and non-governmental organization in order to make suitable contributions towards addressing priority needs of the society (Kandil 2018). In addition, appropriate public participation enables the populace to provide informed and timely input, which ultimately influences the decisions that affect their environment. The activities that require public participation include voting, aspiration for political post, attending meetings, public, private, or political discussion or debate on issues, serving on advisory committees, drafting of policies, signing of petition on a desired government action or policy, volunteering in community activities, and contributing money towards community development (Dietz and Stern 2009).

Furthermore, public participation creates a firm environment in which the encouragement and facilitation of the public bodies charged with decision-making are highly emphasized (Meadowcroft 2004). This empowers the populace in such a way that they are not just observers but contributors of facts and information that ensure fairness in the decision-making process. It also enhances inclusiveness of all groups of people, which include the loudest voice or an underrepresented group. Summarily, public participation tends to enhance trust between parties, reinforces the confidence of stakeholders, and results in an efficient and implementable decisions that reflect general values and interest and also offer benefits for people. It also tends to enhance the faith of the populace in the government, as well as aids better and justifiable outcomes of decision-making and policy formulation (Kandil 2018; Meadowcroft 2004).

Public participation is the process by which the population, either as individuals, groups, and communities, interrelate with the state and other nonstate actors in order to impact decisions, policies, programs, and legislation, and oversight service delivery, development, and other matters

concerning their governance and the ecosystem. It is extensively known as a major feature of project planning and monitoring, policy-making, civic responsibility, and environmental processes (Kandil 2018b; Andre et al 2006). For public participation to be distinctively meaningful, the following essential elements have been identified as critical factors that are capable of successfully integrating the populace in the decision-making process. These are: influence, sincere listening, early involvement, fair and open dialogue, mutual learning, representativeness of public values, inclusiveness, etc. Equally important is the understanding of human values, motivations, and paradigms of the citizenry as well as an understanding of the dynamics of relationships and the structures surrounding government and public interaction (McCoy et al. 1994).

Tools for Public Participation

Public participation encompasses a variety of approaches, processes, and tools. Often times, participatory approaches in public decision-making are usually classified along a continuum, which spans from nominal participation (information exchange) to full participation (comanagement) as described in Table 1 (Krishnaswamy 2012). In between these two ends of the continuum lies the opportunity that enables consultation and collaboration among the relevant stakeholders. Determining the approach and expected level of participation is strongly related to the objectives and peculiar context for which the stakeholders are being involved in the process. It is inadequate to assume that a roundtable discussion or survey is sufficient on the basis that it has been used in a community in the past (Empel 2008; Kandil 2018b).

Several valuable tools have been developed to help determine the appropriate level of public engagement needed to ensure effective participatory processes such as the public participation matrix and Vroom–Yetton decision tree (Robinson 2003). It is recommended that the service of experienced experts be sought when designing

Public Participation, Table 1 Continuum of public participation

	Information exchange	Consultation	Collaboration	Comanagement/ Control
Description	Information is communicated primarily in one direction, with limited opportunity for dialogue	Public opinions are sought and considered in expert or managerial decision-making. Information flows in two directions but decision-makers not obliged to integrate comments received	Representatives of the public are actively involved in developing solutions and directly influencing decisions. This usually involves iterative activities, dialogue, and in-depth working relationships with more focus on joint responsibilities	Decision-making authority and sometimes responsibility for organizing public participation is partly or wholly delegated directly to the public or their representatives
Examples	Discussion paper, comment sheet	Public hearing, survey, open house	Round tables, workshops, public advisory committees	Community forest board

Source: Krishnaswamy 2012

1) Does the manager have enough information to make high quality decision?

2) Is the problem structured in a way that there is room for alternative solutions?

3) Is public acceptance of the decision critical to effective implementation?

4) If public acceptance is required, is it reasonably assured if the manager decides alone?

5) Are the public and stakeholders willing to engage in a dialogue in order to improve the situation?

6) Would the quality of public input be improved if learning occurs among the public and stakeholders about the issues?

Public Participation, Fig. 1 Vroom-Yetton decision tree for selecting public participation methods. (Source: Robinson 2003)

Public Participation, Table 2 Interpretation of Vroom–Yetton decision tree

Code	Description	Approach/Interpretation
A	The manager solves the problem or makes the decision alone without public involvement	Information exchange
B	The manager seeks information from segments of the public but decides alone in a manner which may or may not reflect public influence	Consultation
C	The manager shares the problem with separate segments of the public or stakeholders, getting ideas and suggestions, and then decides which reflects public influence	Collaboration: Involve public with separated stakeholder segments
D	The manager shares the problem with the public and stakeholders as an assembled group, getting ideas and suggestions, and then decides which reflects public influence	Collaboration: Involve public with mixed participants
E	The manager shares the problem with the public and stakeholder as an assembled group, and together the manager and the group attempt to reach agreement on a solution	Comanagement/control

Source: Robinson 2003

and determining the public participation tool. The Vroom–Yetton decision tree is illustrated in Fig. 1 as an example of tools for determining the depth of public participation. The decision tree was developed by Victor Vroom and Phillip Yetton in 1973 as a model for contingency decision-making in organizations. The original goal was to facilitate the engagement of subordinate officers in corporations to help improve quality of decision-making. The model was however later modified to give room for participation of the general public in decision-making (Robinson 2003). Tools to build different types of participation range from stakeholder consultations and public hearings to community watchdog groups and public–private partnerships (Moseti 2010). These tools can also be classified as direct and indirect tools. Indirect tools include comment sheets, toll-free lines, referenda, and surveys, while direct tools include public advisory committees, focus groups, workshops, round tables, open houses, and public hearings. Nowadays, there are emerging tools which are usually electronic or web based and are designed specifically to convey information or technical details visually (Krishnaswamy 2012) (Table 2).

In organizing public participation, it is also helpful to assess the performance of the tools used based on criteria and indicators for effective engagement process. In this case while criteria broadly measure the key factor in the public

participation process like anonymity and relevance, indicators assess aspects of criteria (Krishnaswamy 2012). Table 3 below categorizes the criteria into three core elements of public participation: breadth, depth, and outcomes. Breadth of the public participation addresses the level of adequacy of incorporation of public values in the decision-making process. The depth evaluates the quality of engagement of the public including the level of interaction and exchange of opinions between participants. The last core element “outcomes” involves the measurement of the extent to which the shared ideas and perspectives relate to the goals of conducting the participatory process (Krishnaswamy 2012).

Summary

The potential of the populace in participating in decisions that affect them and the environment can be determined by the disposition of government officials to engage the general public as well as the efforts of the populace to participate. It is important to note that policy decisions are not made in a linear and organized manner, but of a multifaceted procedure with an ever-changing condition. For the public to believe the validity of their input, public participation must be incorporated into the larger culture of decision-making. Public participation cannot exist merely as a series

Public Participation, Table 3 Core evaluation elements of successful participation tools

Core elements	Criteria and indicators
Breadth	<i>Representation</i> – Incorporate a wide range of public values
	<i>Accessibility</i> – Be available to all public interests
	<i>Renewal</i> – Allow for new participants over time
	<i>Anonymity</i> – Protect participants' identities when necessary
Depth	<i>Listening and Dialogue</i> – Foster a two-way flow of information
	<i>Flexibility</i> – Be flexible in scope
	<i>Deliberation</i> – Provide opportunities for frank and open discussion
	<i>Transparency and Credibility</i> – Promote and make available in a clearly understandable form; independent input from scientific and other value-based sources
	<i>Relationship Building</i> – Promote positive personal and institutional relationships
	<i>Relevance</i> – Influence the decision-making process
Outcomes	<i>Effectiveness</i> – Improve the quality of decisions
	<i>Mutual learning</i> – Contribute to all participants' knowledge
	<i>Reciprocity</i> – Reward or provide incentives
	<i>Cost-effectiveness</i> – Output or outcome is cost-effective relative to inputs

Source: Krishnaswamy 2012

of singular events where only the loudest voice is heard. There must be an inclusive community of participation where stakeholders have equal voice and play a continuous role in the policy-making process.

Public Procurement and CSR

Jellie Molino

University of Turin, Turin, Italy

Synonyms

Smart public procurement; Social and responsible public procurement; Strategic public procurement; Sustainable public procurement

Description

The link between public procurement and corporate social responsibility (CSR) is not something new. McCrudden (2006) had in fact argued on the “use of public procurement in the pursuit of CSR” more than a decade ago. He even traced its connection from social policies in the nineteenth century that integrated “social and environmental concerns in business operations” through, for example, the prohibition of child labor under the US Fair Labor Standards Act of 1938, and until the development of “CSR-supportive policies” in public procurement in the European Member States, for example, introduction of social clauses in government contracts (Belgium), inclusion of social and environmental consideration in public procurement contracts (French), and significant amount of green public procurement, that is, 40–70% of published tenders on Tenders Electronic Daily in 2004 (Austria, Finland, Germany, the Netherlands, Sweden, and the UK). Accordingly, public procurement, especially public procurement law, provides an excellent treatment on the subject matter of CSR, the level of government authority, and the place of performance of contract (McCrudden, as cited by Snider et al. 2013).

Introduction

This contribution will not attempt to reargue on the important links between public procurement and CSR, albeit, provide a two-pronged approach on how to strengthen their links. The first prong (which is the most common) discusses the role of public procurement as a strategic tool to promote CSR by analyzing the existing public procurement policies and practices that may encourage and/or require private suppliers or contractors to strengthen CSR in their operations. The second prong focuses on the use of the purchasing powers by public procurers by looking at the possibility of maximizing CSR as an “incentive-based market-mechanism” in which the government acts as a purchaser (McCrudden 2006), and thereby, transform any government agency to a potential “CSR Champion.”

In doing so, this entry highlights the methodologies, including best practices, in public procurement that promote CSR among private suppliers in the public procurement market, while assessing the potentiality of adopting these practices in public procurement with an objective of maximizing the capability of business sectors and the government to “mutually shape each other” in a symbiotic relationship (Gammage and Novitz 2020) for a more sustainable future.

Public Procurement as a Strategic Tool for CSR

Public procurement, also known as “government acquisition” or “government contracting,” has evolved from a traditional “process- and transaction-based approach, i.e., the simple process of obtaining the needed supplies or services through contractual means, to the most recently accepted approach of using public procurement as a strategic function of government” (Lloyd and McCue 2004), an approach that aims not only to “mirror the private sector purchasing” (Guinepero, 2000, as cited by Lloyd and McCue 2004) but, more importantly, to achieve policy objectives such as climate mitigation, innovation or social inclusion, investment, and competitiveness (European Commission 2019).

While the term “strategic public procurement” is often used as a synonym for “sustainable public procurement,” the former indicates a broader scope, since, it focuses not only on the economic, social and environmental goals but also on other “horizontal issues” such as innovation and other public procurement policy considerations, that is, green public procurement (GPP), socially responsible public procurement (SRPP), and public procurement for innovation (PPI) (Handler 2015).

Corporate social responsibility (CSR), on the other hand, refers to the “actions that appear to further some social good, beyond the interests of the firm and that which is required by law” (McWilliams and Siegel 2001), which can either be “explicit,” that is, voluntary and formalized corporate policies on responsibility to promote social interests, or “implicit” (mandatory social obligations for companies arising from social consensus, i.e., prohibition of child labor) (Matten and Moon 2008).

Interestingly, however, the important role of public procurement as a CSR driver (OECD 2020) is significant only in enhancing “implicit CSR” by ensuring compliance by private suppliers or contractors to the requirements of the government in promoting “social interests” such as the prohibition of child labor. In fact, in some cases, companies that are already participating in public procurement do not find it necessary to pursue other “voluntary philanthropic activities” such as for example payment of “living wage” together with retirement and health benefits (Burton et al. 2000, as cited in Snider et al. 2013) since compliance alone to the minimum social standards, for example, payment of minimum wage is already profitable (Snider et al. 2013) and sanctions such as debarment or exclusion from future government contracts are imputed only in case violations of the minimum government standards, that is, criminal convictions or grave misconduct even without conviction such as bribery (Arrowsmith and Maund 2009).

The challenge, therefore, is to enhance the promotion of “explicit CSR” through public procurement by not only requiring “more social responsibility” from private companies with whom the government is doing business but also

promoting that doing so is, in fact, more profitable.

Governments around the world spend an estimated US\$9.5 trillion in public contracts every year (World Bank 2020), which represents 12–14% of GDB on average across OECD countries (BHRRC 2017; European Commission 2019) and 15–25% of non-OECD (developing) states (UNHR 2011; World Bank 2020). The USA alone spends an average of USA\$350 to USA\$500 billion a year, which makes it largest single purchaser in the global economy (BHRRC 2017).

In the European Union, public procurement accounts for 40% of public spending, or nearly EUR 2000 billion/year (European Commission 2019), which gives the governments of Member States a significant influence over the markets, where they represent a large part of the market share (i.e., 14% of EU GDP) (Maitre-Ekern 2018).

It is not a rocket science to therefore conclude that the combined government purchasing power has the potential of influencing the market, more particularly, the economic operators that participate in public procurement market (i.e., bidders, suppliers, tenderers, contractors) to do more “socially responsible activities” by incorporating “more explicit CSR” as requirements for competition in accessing public procurement opportunities. In fact, the role of public procurement as a “strategic instrument” to “respond to social, environmental and economic objectives” has already been identified by numerous international and national organizations such as the European Commission (2017). There are already recorded best practices in public procurement that ‘influences CSR (1) through standards that apply to any firm seeking to sell to the government; (2) through contracting process in proposal evaluations; and (3) through contract specifications and deliverables that accomplish CSR-related purposes’ (Snider et al. 2013).

In Europe, for example, public authorities have started to use their purchasing power in introducing sustainability in public procurement such as the use of Green Public Procurement (GPP) criteria (Maitre-Ekern 2018), for example, the use recycled materials in new products in selected

government procurement activities in Germany, the Netherlands, and Finland (Tojo and Thidell 2018).

Under the 2014 EU Procurement Directives, sustainability considerations may be incorporated directly in public procurement as part of the award criteria (e.g., fair trade certification as an award criterion) or conditions in the performance of the contract (e.g., where a supplier reduces the carbon emissions associated with production or delivery of a product or service, or a works contractor employs disadvantaged workers or trains apprentices) provided that these considerations are “link to the subject matter” of the procurement and can be verified, or indirectly by encouraging companies to change their general corporate practices (Semple 2016) through adherence to voluntary policies such as eco-labels or code of conduct in regulating product design features by incorporating environmental standards in product description, that is, the specific characteristics of the goods and services that they are offering the government (which is the common practice in bid/tender evaluation), and in “product and processing methods” or on how the product is produced, that is, including issues on emission during production and transport (Bugge et al. 2020).

In other countries, such as Japan, public procurement is used as a tool not only to call for the contributions of corporations in delivering sustainable development goals on environmental issues, fairness, and free competition, including responsible procurement, adherence to ISO 26000 on social responsibility and ISO 20400 on sustainable procurement as reference but also to introduce green purchasing to small- and medium-sized companies as part of the supply chain through a simplified system of self-commitment, evaluation, and reporting concerning environmental management under the name “Eco-action 21” in 1998 (Kozuka 2020). Government agencies are already required to (i) facilitate green procurement, (ii) introduce environment accounting, and (iii) promote environment reporting (id).

While most of GPP criteria and ecolabels or certification requirements schemes remain voluntary (e.g., Energy Star, use of life cycle costing),

some standards are, in fact, already mandatory through horizontal legislation, that is, mandatory energy performance standards (MEPS) set under the EU Ecodesign Directive, sector oriented laws on chemical restrictions (packaging, electronics), and the EU law and policy for conflict minerals, or they are already the “de facto market requirements” (Dalhammar et al. 2018).

The “environmental turn” in public procurement had already led to the adoption of several EU green public procurement framing measures, many of which were actually binding obligations on contracting authorities to procure “green”: specific mandatory GPP rules contained in the Energy Star Regulation (2008), to buy energy-efficient IT office equipment; the Clean Vehicles Directive (2009), mandating environmental friendly vehicles; the Energy Performance of Buildings Directive (2010), introducing an obligation for new buildings owned and occupied by public authorities to be “nearly zero-energy” by end of 2018; and the Energy Efficiency Directive (2012), to purchase energy-efficient buildings and equipment of the highest energy labeling class (Schebesta 2018).

Aside from the direct economic benefits in the form of energy savings and increased demand, one possible spillover from green public procurement is the adoption by private developers of certification scheme like the Leadership in Energy and Environmental Design (LEED) green building certification program, for example, the adoption of the US Green Building Council’s LEED standard in the construction of green building in selected cities in the State of California (USA) resulted not only to the adoption of the said standard by the private-sector in the government contracting market but also by the supplier investments in green building expertise (Simcoe and Toffel 2012).

Government can even trigger the development of new and more energy-efficient products on the market through public procurement for innovation (PPI). Manufacturers who are hesitated to develop better products due to demand uncertainty may participate in PPI that guarantees a certain amount of new products will be bought by the government, for example, the USA and

Sweden have successfully used procurement to induce the launch of more energy-efficient appliances such as fridges and freezers (Dalhammar et al. 2018).

Since public procurement market is a locus of corruption and other poor-governance practices (Popa 2018), which are manifested by the usual “red flags” for corrupt practices such as single-bidder, that is, a simple indicator for corruption risk index (CRI) or other complex CRI indicators, for example, no call for tender, restricted procedure, risky evaluation criteria, extreme submission period, and extreme decision period (Fazekas and Kocsis 2017), governments can implement institutional reforms toward diversification of interactions between public and private actors through, for example, explicit quantitative targets for diversification, as well as auditing of close connections in public procurement in order discourage and disrupt corrupt interactions (Popa 2019).

Governments can do all of these, not only by acting as the “buyers” but also as public procurement policy formulator, implementer, and regulator. Governments can, therefore, do more than just, for example, incorporate a clause on the protection of human rights in the contract conditions for government contracting. They can, in fact, extend the requirement in mitigating the risks of child labor, forced labor, and human trafficking not only in the business operation of their winning bidders or tenderers but also within the “supply chains of the companies with whom they do business” (UNHR 2011). They can even adopt the model public procurement provisions such as mandatory due diligence reporting obligations for relevant public bodies, inclusion of modern slavery provisions in social clauses of public procurement, and mandatory exclusion provisions for suppliers involved in modern slavery violations or for failure to report under mandatory reporting provisions (BHRRC 2017), and even extend these requirements not only in their own business operation but also within their supply chain, such as in the case of the United Kingdom Modern Slavery Act of 2015 (Johnston 2020).

Although legislative intervention is often needed to perform the abovementioned activities

and overcome the limited scope for the promotion of sustainable development such labor standards for workers in the global supply chains (Rühmkorf 2020), government contracting is not, however, precluded from adopting international standards such as the ILO Convention on Labor Clauses for Public Contracts, which promotes socially responsible public procurement by requiring bidders and contractors to align themselves with the locally established prevailing pay and other working conditions as determined by law or collective bargaining, or implement some of existing policy approaches that align with international standards such United Nations Guiding Principles on Business and Human Rights and the OECD Due Diligence Guidance for Responsible Business Conduct (UNHR 2011), and, thereby, mitigate the adverse social and environmental externalities generated by multinational enterprises (MNEs) that take advantage of weak accountability systems and poor enforcement of laws in developing countries, using them as safe havens for profit-making at the expense of sustainability (Zhao 2020).

To address the social and environmental problems arising in global supply chains, for example, human trafficking, hard solutions in disclosure and due diligence are already replacing voluntary initiatives not only to reduce their adverse impacts of these problems but also to enforce sanctions, more particularly focused on the liability of the actor with the most control in the supply chain (Villiers 2020).

Songi and Dias (2020) even argued on the importance of a sanction-based regulatory approach or a hybrid regulatory model that combines a mixture of both mandatory and voluntary approaches in sustainability reporting regime using a “comply or else” model, instead of either “comply or explain” or “apply or explain” self-regulatory model in order to address the lack of maturity in defining corporate performance measures of values in most jurisdictions. They justified this model using the case of Africa where companies are not required to engage in corporate sustainability activities under the prevailing CSR law (The Companies Act) but are, however,

mandated to embrace corporate sustainability under the Broad-Based Black Economic Empowerment Act, 69 Act No. 46 of 2013 by requiring South African-based companies to engage in Preferential Procurement Policy in favor of local companies (Mongalo 2020).

Preferential treatment is in fact becoming one of the modalities for the implementation of explicit CSR. In the case of the UK, for example, certified companies are given preferential treatment under the UK Public Services (Social Value Act of 2011) due to the importance of certification schemes not only as a proxy for social value but also as an effective regulatory tool in reconciling sustainability concerns with the functional mechanisms of market economies (Möslein 2020).

CSR policies are already becoming an important part of government contracting as shown by the inclusion of social and environmental impacts as part of the award criteria to be weighed against price (e.g., by allowing a 10% price preference for tenders offering social benefits) (Arrowsmith and Maund 2009). In fact, suppliers, for example, in public utilities can be excluded for anticipated failure to fulfill certain CSR requirements and public procurers can even use these criteria – CSR requirements – to narrow down registered suppliers to a “preferred list” (Id.).

Aside from preferential treatment for CSR compliant companies, public procurement is already used as “an extraordinarily adaptable tool” to increase CSR compliance through enforcement measures such as disqualifying non-compliant companies from being awarded government contracts (Snider et al. 2013). The question, however, is if the government can use legal measures to promote sustainable corporate behavior through an ex ante regulation, that is, regulatory minimum standards or mandate disclosure, and ex post litigation, that is, filing a case for damages for corporate misbehavior (Shapira 2020), why does the government remain passive in mainstreaming the same standards in the selection of private companies with whom it is doing business despite the recorded best practices in promoting CSR compliance through public procurement.

Public Procuring Entities as CSR Champions: A “Walk-the-Talk” Strategy

The term “procurement” was first used in a regulatory term in the 1960s, and the use of “tenders” in the selection of suppliers and contractors became a common practice only around mid-1970s, which replaced the then practice of securing external supply of goods and services like private enterprises through either “direct procurement” (Morlino 2019) or “sole-source negotiations” (Wittie 2003).

Prior thereto, public procurers acted more like private enterprises than contracting administrators due to the absence of a public law-type procedure, a very limited market research, and a practice of identifying contractors without a predetermined public procedure (Morlino 2019). The “histories of protracted wresting” between the government and contractors in preventing delays in the delivery of public works and services (Yukins 2017) aggravated by major corruption scandals in the 1990s (Morlino 2019) has resulted to making public procurement as one of the highly regulated (Prat et al. 2012) and legislated government activities.

Unlike, however, with other government functions, public procurement activities call for two-tier governmental functions – purchasing and regulating (Arrowsmith and Kunzlik 2009). In assuming one or a combination of these roles, the common mechanisms that public sector adopts in promoting CSR include (1) regulating by defining the minimum standards for business performance embedded within the legal framework; (2) facilitating by stimulating companies to engage in SR agenda or to drive social and environmental improvements; (3) partnering as a participant or facilitator, for example, public private partnership; and (4) endorsing CSR through various means, that is, CSR in policy documents or direct recognition of the efforts of individual enterprises through award schemes (Choi 2010).

As procuring entity and a regulatory agency, governments can even participate in the development of standards in describing specificity the materials and products that they need to purchase, while regulating the use of the said standards to

serve a more varied array of purposes, including protecting public health and safety by giving voluntary standards the force of law, integrating public regulatory requirements with private standards regimes, specifying the technical details of regulatory requirements, or helping government officials to evaluate regulatory compliance and enforce the law (Bremer 2019).

What is lacking, however, is for the government to leverage on its purchasing power in order to regulate the transformation of the traditional approach in public procurement as a “compliance driven and reactive” CSR tool through sanctions like debarment for corrupt practices or disqualification/ineligibility for pass-performance to a more proactive “CSR-centered” legislation (Okoye 2020).

Public authorities can, in fact, require not only from their contractors or suppliers the integration of “explicit CRS” in their business strategies, but, more so, their integration in their own management and operations the explicit CSR requirements that they are requiring from their business partners, thereby, making them a model for CSR integration, especially in cases where they likewise play the role of shareholders.

In some countries, government is also a shareholder (e.g., countries in Nordic economies), wherein government and public pension funds are considered as “major socially responsible investors in Europe,” thereby making public entities such as states and municipalities as important shareholders in both private and listed companies (Mahonen and Johnsen 2020). Nonetheless, it does not necessarily ensure that sustainable corporate practices are adopted in companies where a government is a shareholder. In fact, there are countries even with a “clean and green image” like New Zealand where sustainability considerations are yet not central in their corporate governance that is still grounded on prioritizing sustainability next only to shareholder primary norms of promoting wealth maximization (Watson 2020).

The challenge, therefore, is not only on defining what CSR is (Pilato 2020), but more on what CSR means when applied in a government setting such as public procurement.

Public procuring entities (i.e., government agencies, institutions, or local government units) may, in fact, adopt the best practices on “responsible business conduct,” a conduct which calls for companies to become socially responsible either by “voluntarily” integrating social, environmental, ethical, consumer, and human rights concern in their business strategy operations (OECD 2020) and not just simply apply the minimum requirements of the law in government contracting. In procuring goods or services, public procuring entities are acting as economic actors, hence, they are expected to behave responsibly and lead by example in implementing the main international corporate responsibility instruments not only for public interest and accountability of public spending but also for the legitimacy of public policies on responsible business conduct (UNHR 2011).

Public procuring entities should lead by example in integrating due diligence criteria in the selection of their suppliers and contractors (UNHR 2011). If public interest required mandatory disclosure from private firms of their group policy in relation to “environmental, social and employee matters, respect for human rights, anti-corruption and bribery matters,” including the outcome of these policies; the risks related to these matters and how the group manages those risks; and the non-financial key performance indicators relevant to the particular business, in their annual accounts (Clarke and Anker-Sorensen 2020), as part of hard regulatory requirements to steer corporate behavior (Chiu 2019), the same mandatory requirements should be used to “steer” the same behavior from public procuring entities since they are also acting as economic actors in a public procurement market.

In EU, for example, the EU Non-financial Disclosure Directive already includes corporate reporting obligations to report the development, performance, position, and impact of its activity to environmental, social, and employee matters, respect for human rights, anti-corruption, and bribery matters, which is the same concept of materiality for environment and social impact disclosures in accordance with the Global Reporting Initiative’s Reporting Standards (GRI) (Chiu 2019).

The question is why not subject public procuring entities to the same reporting requirements like the case of state-owned companies in China and Sweden (www.globalreporting.org) or the case of international organizations like the United Nations Office for Project Services (www.unops.org), which have voluntarily submitted their operations to GRI reporting standards.

Adopting international standards like the GRI standards in government contracting will not underline sustainability in the organizational operation of public procuring entities but will also promote sustainability to their contracting private companies, and this can even extend to overseas partners of their suppliers, and thereby promote extraterritorial sustainability (Snider et al. 2013).

Summary

If it remains a challenge to promote both explicit and implicit CSR to private companies, it is even more challenging to integrate them in government operations, more particularly in public procurement.

Some of the challenges include ensuring that the legal framework for public procurement provides the mechanisms to address not only environmental issues through sustainability requirements in the technical evaluations of the submitted proposals, tenders, or bids but also social issues such as child labor, forced labor, and human trafficking in the operations of private companies through contractual provisions in the entire supply chain.

Strong CSR policies in government contracting require a strong monitoring and verifying compliance mechanisms, coupled with an effective engagement among stakeholders (i.e., business, social partners, and civil society) in strengthening sustainability in public procurement, while building capacity and raising awareness among public officials on sustainability integration in public procurement and strengthening international collaboration on responsible procurement through sharing of best practices and exchanging of tools and information risks related

to products and markets, including follow-up and monitoring (UNHR 2011).

To address this challenge, public procurement should not be a function limited to contracting officials. Like most CSR champions, the public procurement unit must have sustainability team that will provide an up-to-date information on the unit's sustainability objectives, including how the unit is managing its ethical strategy, and an up-to-date information about the availability of environmentally preferable goods and services, while ensuring that the sustainability strategy is communicated throughout the organization to get the involvement of all units in developing sustainable procurement strategy that will ensure capacity building within the procuring organization (Theron and Dowden 2017), and adopting voluntary CSR reporting standards like GRI or even UN Global Compact can be a first step toward a more socially responsible government contracting.

Definition and Fields of Public Relations

The term public relations (PR) can be traced back to the end of the eighteenth century and is supposed to be introduced by Thomas Jefferson (Gackowski 2017). However, modern PR started at the beginning of the twentieth century with companies defending their reputation in newspaper articles. Later, Boston University was the first to establish a School of Public Relations in 1947 (Tikkanen 2022). Originating from the USA, PR expanded around the globe, for example, in Germany, five phases from the early formation in the 1960s, over expansion in the 1990s, up to a sophisticated differentiation can be observed (Köhler 2018). Today, PR is seen as a fundamental part of the general strategy of a company and encompasses all communication activities toward different stakeholder groups (Schmidt and Rennhak 2020). However, since research on PR is scattered around disciplines and depends on cultural context factors, different definitions of the phenomenon are discussed (Schmidt and Rennhak 2020). In communication research, one broadly accepted definition is given by Cutlip et al. (2000). According to the authors, public relations is a management function that establishes and maintains beneficial relationships between an institution and the public addressing the success of the institution. By referring to different criteria, PR can be segmented into various areas (Laskin 2014). Among others, the relationship management of stakeholders on financial

markets is the focus of many corporations. Accordingly, the term investor relations (IR) or financial communications emerged for this special field of activities in PR.

In the USA, IR is supposed to be used for the first time by General Electric in 1953, while BASF AG was the first company in Germany to have established an IR department in 1988 (Gackowski 2017). Reflecting the increased separation of ownership and control in modern economic systems, IR activities developed in line with the emergence of organized financial markets at the beginning of the twentieth century (Laskin 2018b). Furthermore, the rise of IR over the decades is closely linked to increased financial market regulation in response to financial market crises (Laskin 2018b; Gackowski 2017): The first period of IR began after the Great Depression in the 1930s. Security Law was enacted to diminish frauds in the issuance and trading of financial instruments by sharing information with financial market participants. The second milestone for the increased role of IR dates back to the Enron case. Subsequently, disclosure regulation on financial data was extended. Additionally, with the Sarbanes–Oxley Act in 2002, corporate governance structures were modified and sanctions for misbehavior of managers and board of directors were introduced. Finally, financial market regulation was improved fundamentally after the financial crisis in 2008, which enhanced the role of IR further. Because of the stricter regulation and rapid digitalization, sharing financial data became less important for IR in favor of nonfinancial disclosure activities. The new focus was on relationship building by reporting on the process of value creation (Doan and McKie 2017).

Definition and Perspectives on Investor Relations

Various definitions of IR appear in academic research, because of the interdisciplinary character of the research topic (Doan and McKie 2017; Bassen et al. 2010). First, IR can be defined as an organizational unit in a corporation that focuses

Public Relations and Finance,

Fig. 1 Investor relation as functional unit (source: owns figure)

on financial communications, facilitating the exchange of funds on financial markets between lender and borrower (see Fig. 1). This definition is predominant in communication science (Köhler 2015). Financial communication can directly address the two target groups: institutional and private investors (see Fig. 1). In addition, IR communicates indirectly to these two groups via financial media and financial intermediaries (see Fig. 1). Today all stock-listed corporations maintain close relationships to financial market participants. The traditional role of the Investor Relations Officer (IRO) turned from mere communicational to a more financial one (Hope et al. 2021; Bassen et al. 2016; Laskin 2009; Rao and Sivakumar 1999). Furthermore, IROs are professionally organized in national umbrella associations (e.g., National Investor Relation Institute (NIRI) in the USA; Deutscher Investor Relations Verband (DIRK) in Germany). Since IR is an omnipresent phenomenon around the world and is becoming increasingly important as a profession, communication research is mainly conducted in the areas of relationship building and reputation management (Köhler 2015; Laskin 2014; Brennan and Tamarowski 2000; Rao and Sivakumar 1999). Communication scholars largely use qualitative research methods (Doan and McKie 2017).

IR is also a field of research in corporate finance literature. Correspondingly, a second definition based on an activity-based concept of IR is used (Soppera 2019). This definition of IR comprises all kinds of communication activities on financial markets and focuses on relationship-building with financial market participants. Hence, the one-sided flow of information in the first definition of IR (see Fig. 1) is extended to a bilateral exchange of information. This definition is in line with the activity-based definition of corporate finance (Merbecks 2022) and opens up avenues for more interdisciplinary research on IR (Laskin 2018b; Doan and McKie 2017). The business stream on IR research formulates explanatory models and tries to test them by using quantitative methods (Doan and McKie 2017; Kirk and Vincent 2014).

Initially, the existence of IR was explained in the context of the (information) efficient financial market hypothesis (Fama 1970). By providing decision-relevant information to the market participants, IR is the cornerstone for all three levels of efficient markets (Laskin 2018b). Subsequently, New Institutional Economics introduced market imperfections into the basic neoclassical model of perfectly competitive financial markets: information risks, asymmetric information, and transactions costs. Consequently, researchers

were able to explain the functions of IR in greater detail by referring to conflicts of interest on financial markets. These conflicts occur due to the asymmetric distribution of information and general informational risks and are based on signaling and agency theory (Soppera 2019; Köhler 2015). Disclosure of decision-relevant information to the financial community is a market-based instrument to alleviate financial market imperfections (Soppera 2019). The benefits of disclosing information to financial markets are analyzed theoretically and empirically based on two cause-effect theories: First, disclosure of information is supposed to have indirect influence on stock prices and financing costs (Brennan and Tamarowski 2000; Farragher et al. 1994). Second, disclosure activities are supposed to have a direct impact on the firm's shareholder value (Bassen et al. 2010). Many quantitative studies are conducted to show the impact of IR on market variables by using large databases (Doan and McKie 2017).

Moreover, the functions performed by IR received attention in corporate governance literature (Crifo et al. 2019; Köhler 2015). IR is supposed to act as a corporate governance mechanism on financial markets for the harmonization of shareholder and management interests. In addition, in response to many corporate scandals, the alignment of interests of other stakeholders became important as well for the IR and became a research topic. Besides, the rise of the corporate sustainability movement accelerated the governance functions undertaken by IR (Crifo et al. 2019). Nonfinancial information on environmental, social, and governance (ESG) factors is relevant for socially responsible investors. Hence, the role of IR in transforming financial markets by building reputation on Green Finance is analyzed in some research projects (Fieseler 2011).

Further insights into the functions performed by IR and recommendations for the design of IR result from behavioral finance approaches. Behavioral finance questions the rationale decision-making paradigm used for the explanation of IR in the financial market models introduced above. Instead, financial market anomalies are in the lime-light of this part of the research. Based on new findings from behavioral analysis, not only

decision-relevant information but expectations of financial market participants should be addressed primarily by IR (Soppera 2019; Köhler 2015).

Although the interdisciplinary character of IR is obvious, current IR research remains separated between the communication and the business discipline. Hence, practical IR management lacks sufficient academic support on strategizing and operations. A more integrated view on IR incorporating marketing, finance, communication, and financial market law offers research avenues for further research (Binder-Tietz et al. 2021; Doan and McKie 2017).

Investor Relations Practices

Functions and activities of IR practices differ broadly across countries, industries, and firms (BNY Mellon 2020; Karolyi et al. 2020; Laskin 2006). Over the last decades IROs have become an integral part of strategic management and are performing a leadership role in many corporations (Maas 2021; Hoffmann and Binder-Tietz 2020). Therefore, referring to marketing research seems to be promising for a more detailed analysis of these numerous activities. This conceptualization of IR based on marketing theories is promoted by the German IR research strand (Streuer 2021; Schiereck and Hinrichsen 2021; Köhler 2015; Link 1993), which in a broader sense defines IR as financial marketing management. This marketing perspective on IR is beyond the above proposed narrow functional definition of IR that focused on communication activities in financial markets by a distinct corporate function. In addition, this extended academic perspective on IR matches the definitions of IR practice introduced by umbrella associations (NIRI 2022; DIRK 2022). Financial marketing management is performing an important role on non-perfect financial markets by reducing uncertainty and conquering other frictions that occur in the context of completing and exchanging financial contracts (Link 1993; Ross 1989). From a marketing perspective, IR management is performing a strategic management role by setting strategic goals and defining targets (Hoffmann et al. 2021; Tam

et al. 2022) in line with the corporate strategic long-term guideposts (see Fig. 2). Basically, IR must support the strategic goal of solvency which is central to financial management (see Fig. 2). The solvency goal offers guidance to more detailed targets in IR, for example, reputation or the market value of the corporation (see Fig. 2). A marketing perspective on IR also encourages for further research on the long-term value proposition (Laskin 2011) and the differentiation between the information-seeking behavior of different stakeholder groups (Doan and McKie 2017).

IR conceptualized by financial marketing management offers different ways for the classifications of IR activities in practice. The most common classification in practice is the distinction between shareholder and creditor relations (see Fig. 2). Existing literature on shareholder relations is extensive and diverse. Therefore, referring to the company’s life cycle model offers guidance for the organization of the main topics currently addressed:

- Early Stage: Performing IR for a start-up corporation focuses on emotions and confidence

and requires knowledge for legal requirements. Hence, researchers address the relevance of storytelling for successful funding in entrepreneurial corporations (Byrum 2018).

- Growth Stage: Since the role of IR on primary financial markets was neglected in early IR research, the examination of IR activities for the success of Initial Public Offering is currently increasing (Chahine et al. 2020).
- Maturity Stage: Because of the increasing relevance of sustainability goals for investors, public firms are often confronted with shareholder activism. This issue is addressed in detail in current IR researchlikewise (Hoffman et al. 2016; Laskin 2018c).
- Decline Stage: IR is highly involved in delisting decisions of public companies. Hence, a new field of research is emerging grounded on network theory (Schierreck and Hinrichsen 2021).

Although debt market participants are clearly addressed by IR activities in practice as well, empirical evidence on this stakeholder relationship is still in an emerging state and offers avenues

Public Relations and Finance, Fig. 2 Investor relations management (source: own figure)

for further research projects (Kim et al. 2021; Walchshofer 2021). Especially, the growing interest in sustainable finance innovations and the corresponding emergence of the “Green Bond” markets will support the increasing importance of IR’s role in debt markets.

Definition

According to Moore (1995), public value is constituted by the satisfaction of the wishes of the citizens and the community of reference. In the author's view, managers of public organizations can create value in two distinct ways:

- Through the use of financial resources and the authority assigned to them, which are used to produce goods and services designed to satisfy public needs
- Communicating the expected and actual performances to the citizens, to obtain the approval of their work by the community and thus guaranteeing the legitimacy of their action

The following characteristics can be attributed to the public value:

- It focuses not only on the objectives set by the political bodies of public administrations but

also on the expectations of the community in question.

- Its evaluation is not restricted to the analysis of short-term results but goes necessarily from a long-term perspective.

Introduction

Accounting and business administration scholars have long focused on identifying a universal goal, common to all types of organizations, which can be considered as the basic objective for which organizations are established and kept alive. Zappa (1956) has identified this objective in the survival of the organization.

Currently, the prevailing literature on this subject identifies the basic objective of organization and corporate action in the creation and distribution of value. This means that a requirement for the lasting survival of organizations is the creation a higher value than the value of the utilities employed in the production procedure.

The identification of value as the primary end of organizations is a broadly acknowledged approach in the accounting and business administration literature. However, over time this value has been identified and measured in different forms. In for-profit organizations, this value has been identified, for a long time, in the profits to be distributed to the holders of own capital. This value is obtained as a surplus of revenues over costs. The appropriateness of the return of investors is essential for them to preserve their capital investment, thus enabling the organization to survive over time (Zanda et al. 1997, p. 171).

Considering excessively limiting the identification of value in mere profit, some scholars have referred to the value of equity, others at market value, and others to the added value. With specific reference to public organizations, more recent settings focus on *public value*.

To this end, it is useful to propose a brief historical excursus on some of the most relevant conceptual settings on the subject of value. International literature has provided useful contributions on this subject. A milestone can be considered Porter's (1985) value chain. It identifies

the set of activities necessary to design, produce, and sell a certain product/service, including post-sales assistance to customers. These activities allow the company to achieve a competitive advantage compared to its competitors. This "competitive advantage" can be understood as "the search of privileged positions aimed at breaking competition and generating profits" (Guatri 1991, p. 3).

During the 1980s of the twentieth century, theories of value creation and total quality were formulated.

A significant contribution to the subject of public organizations is Moore's (1995) public value model. Other relevant contributions are Normann and Ramirez's (1993) value constellation and Rebora and Meneguzzo's (1990) service quality chain, constituting a re-adaptation of Porter's value chain to public administrations.

This contribution will focus on Moore's (1995) public value model.

For a long period, the assessment of organizations' performance, aimed at identifying a "value" to be attributed to the organization, was carried out mainly based on economic, financial, and equity indicators, which can be found in the financial statements. However, this approach is difficult to apply to not-for-profit organizations. Although no substantial problems are found in the attribution of economic and monetary value to the costs incurred in the production process, the atypical exchange mechanisms characterizing these organizations make it extremely difficult (or, in some cases, impossible) to assign a monetary value to the services provided by public administrations.

Until not long ago, it was customary to attribute to for-profit companies the institutional object of maximizing profit. Therefore, the concept of "value" focused on a specific stakeholder: the shareholder. This approach can be identified with shareholder theory, which postulates the maximization of profit, to be regularly and appropriately distributed to shareholders. Based on this theory, the prevailing interest that for-profit organizations must satisfy is the owners' expectations, since they are the privileged stakeholders, providing the capital necessary for the establishment and survival of the organization, and bear the entrepreneurial risk.

The prevailing attention to the owners' perspective has shown obvious limits, as it neglects to consider that for-profit and not-for-profit organizations are entities, which must meet the needs of a multitude of stakeholders. Each of these stakeholders bears their interests, not necessarily coincident with those of the owners. In this way, stakeholder theory has spread, identifying an objective common to all organizations, that is, the creation of value and its equitable dissemination among the various stakeholders.

The consciousness that organizations are not only a tool for the production of wealth but also a fundamental means for its spread among the various stakeholders is not new in business administration studies. This concept is emphasized in Freeman's (1984) Stakeholder Theory.

The production of value by organizations cannot be oriented only to shareholders; value is a multidimensional concept, whose distribution must take place among several subjects. From this point of view, it can be defined as "a communion of multiple interests, which await appropriate satisfaction" (Bergamaschi 2009, p. 122). In this sense, by value creation, we mean the "adoption of governance choices and management/organizational practices allowing to achieve, over time, results having a higher value than that consumed through the use of goods and services in the production process" (Bergamaschi 2009, p. 122).

The multidimensionality of value makes its identification and measurement highly complex processes for each type of organization, and to an even greater extent, for public administrations. The latter often deliver services free of charge (or at set prices), which do not consent to cover the production costs. Therefore, public administrations are usually not able to autonomously reintegrate the resources consumed in the production process; this reintegration can be done through tax revenues or transfers from other public bodies. The lack of capacity to autonomously reintegrate the resources consumed does not mean, however, that significant and measurable value has not been created for the administered community.

In for-profit organizations, the income is a well-founded instrument to identify the value

produced or destroyed. In reverse, for not-for-profit organizations (and public organizations), it is more problematic to identify this value since there are not always compensating equivalents for the goods and services produced. In these organizations, the concept of value is attributable to the qualitative and quantitative degree of satisfying the needs of individual citizens and/or the administered community. This entails the need for measurements that could not be limited to the monetary meter.

Public value theories have been formulated in this context. Among these theories, it is worth mentioning the following:

- Accenture (2004), assuming that there are two main levers of public sector value (PSV), that is, outcomes and cost effectiveness. It identifies the creation of public values through the production of improved outcomes in a more cost-effective way.
- Rebora and Meneguzzo (1990), assuming that the public administration system is characterized by a high complexity, due to which the various entities located along the value chain (in which value can be produced or destroyed) are weakly connected to each other. In this context, it is not possible to improve the satisfaction of the public services' users by acting exclusively on the entities located downstream of the value chain. These entities, in fact, are in turn "customers" of entities operating at a higher (e.g., regional or national) level. Instead, it would be advisable to first identify the final user of public services and the final products/services. Starting from this identification, it is possible to trace the public value chain, in which various public entities operate. In this way, it is possible to identify the various customers, internal to public administrations, who receive services from the entities upstream in the value chain and who provide services to other entities located downstream in the value chain. This means that the overall improvement of the public services users' satisfaction necessarily implies attention to all the phases in which the public value chain is articulated and to all the entities operating in it.

- And, of course, the theory addressed in this contribution: Moore (1995).

The concept of public value is composite, so it is difficult to provide a univocal definition. It encompasses at least two distinct aspects:

1. The reference to economic value, which has been mentioned previously
2. The reference to social value

Unlike for-profit organizations, whose existence is compounded in the creation of economic value for shareholders and other stakeholders (such as customers, workers), public sector not-for-profit organizations must create value in many other ways, coherently with the above-cited Stakeholder Theory (Freeman et al. 2018). In addition to the economic perspective, they must take into account the needs of citizens, and in general of their community, as well as the political needs arising from the representatives of the community who hold elective offices. The latter perspective is associated with the concept of social value.

While the economic value is obtained from the positive difference between revenues and costs, the social value is obtained by the positive difference between the benefits and the charges related to the activity carried out.

Public Value Creation

According to Moore (1995), public value creation postulates:

- The achievement of institutional objectives, outlined by the governing bodies of the individual organization
- The correspondence of the results produced not only to the objectives defined at the planning level but also to the expectations of the community
- The achievement of these results while respecting efficiency, making the best use of available resources and avoiding their waste

The satisfaction of stakeholder expectations must take place in two ways:

- As individuals
- As a community

Public value is a function of the following elements:

- The outputs generated, in terms of quantity and quality of the services produced
- The outcomes obtained, intended as effects or results of public action
- The level of trust that the organization has succeeded in obtaining
- The certainty that the same organization can satisfy stakeholder expectations also in the future

In the original formulation of public value theory, Moore focused on three main issues (Benington and Moore 2011, p. 3):

1. The role of government in society, interpreted not merely as a service-provider, rule-setter, and social safety net but also as a creator of public value and sharper of the public sphere under an economic, political, social, and cultural point of view
2. The role of government managers, interpreted not merely as bureaucratic clerks and passive servants to their political master but also as stewards of public assets that should suggest to governments what to do with the public assets and how to provide appropriate services to users
3. The techniques needed by public managers, interpreted not merely as procedures aimed at guaranteeing reliability of procedures in public administrations but also as tools helping public organizations to adapt more rapidly to changing environmental conditions

Three main elements emerge from Moore's public value formulation in 1995 (Benington and Moore 2011, p. 4):

- (a) The strategic triangle
- (b) The authorizing environment
- (c) The state authority

As for the first element abovementioned, Moore identifies three dimensions of public value, constituting the so-called *strategic triangle*. This is a diagram focusing the alertness of government managers on three relevant topics (Moore and Khagram 2004: p. 1).

1. What relevant “public value” the organization sought to produce?
2. What “sources of legitimacy and support” would be relied upon to authorize the organization to act and provide the resources necessary to sustain the effort to create public value?
3. What “operational capabilities” are necessary to deliver the desired results?

The strategic triangle is displayed in Fig. 1.

Managers should try to maximize the alignment among the three elements of the strategic triangle, which are seldom aligned in their natural status. Therefore, public managers must constantly try to create a balance among these three elements and must focus on the following aspects (Benington and Moore 2011, p. 4):

- *Defining public value*, that is, clarifying the strategic goals and public value outcomes expected in a specific situation
- *Creating an “authorizing environment,”* that is, an environment in which elected politicians and other stakeholders give their support to the organization, which is necessary to perform the organization’s strategic action
- *Building operational capacity*, that is, get the resources (finance, technology, staff, skills, etc.) required to fulfill the target public value outcomes

Public Value, Fig. 1 Strategic triangle

According to this triangle, strategies for public administrations must meet three tests, that is (Moore 1995, p. 71; Moore and Khagram 2004, Alford and O’Flynn 2009, p. 173):

1. Be focused on the creation of something valuable (i.e., something constituting public value).
2. Be legitimate and politically sustainable. This means that public action must be able to attract resources and support from its authorizing environment.
3. Be operationally and administratively feasible, that is, realizable with the accessible organizational and external capabilities.

As for the second element abovementioned, Moore identifies an *authorizing environment* constituted not only by elected politicians but also by organizations and other stakeholders, whose support is necessary to legitimate public managers’ action.

As for the third element abovementioned, Moore requires the use of *state authority* in the creation of public value. This means that public administrations hold power based on three elements: (a) legislation, (b) money, and (c) authority.

Key Issues

The concept of public value was originally formulated by Mark Moore in 1995 in the book *Creating Public Value: Strategic Management in Government*. At the time, the author aimed to propose a conceptual framework to support public managers in understanding the strategic challenges and choices they had to make. The notion of public value was therefore meant as a tool to help public managers similar to the notion of private value for private sector managers. The development of this framework occurred through several years of commitment with public sector managers from the USA and other parts of the world taking part in executive programs at Harvard’s J.F. Kennedy School of Government (Benington and Moore 2011, p. 1).

Initially, the aim was to import (and, if necessary, to adapt) the “private management knowledge” in the management of public (and

specifically government) agencies. The basic idea moved from the assumption that while the purpose of private managers was to create private (economic) value, the aim of public agencies should be to “create public “social value.” A first problem was to understand what is public value and how to operate for its production. Therefore, the workgroup established by Moore developed the concept of “strategy in the public sector,” which is graphically represented through the “strategic triangle.”

Future Directions

Moore’s (1995) original contribution and his further publications on this topic have stimulated a wide debate on the concept of public value, both at the practitioner and academic levels.

In the meantime, public value has become a widely debated topic and there emerged other meanings of this concept, different from the original Moore’s formulation. The main arising significances of public value are summarized by Alford and O’Flynn (2009) and see public value as:

1. *Paradigm*
2. *Rhetoric*
3. *Narrative*
4. *Performance*

Public value can be understood as a *paradigm*, that is, as a “big idea.” This point of view is shared by Stoker (2006), who asserted the emergence of a public value management paradigm aimed at balancing democracy and efficiency; by Christensen and Laegreid (2007), who argued that a public value paradigm has developed in Britain and New Zealand as a post-New Public Management paradigm; and by O’Flynn (2007), who focused on the managerial outcomes of a public value paradigm.

Public value can also be understood as *rhetoric*, that is, as a rhetorical strategy aimed at protecting the interests of public managers. This point of view emphasizes the great power of rhetoric that can convince its audience.

Public value can be understood as a *narrative*, that is, “a story of the world of public managers” (Alford and O’Flynn 2009, p. 182). There are many interpretations of public value as a narrative. Among them, this interpretation of public value can emerge from two different aspects of Moore’s contribution: (a) the relevance of paying attention to the stories of public managers involved in the Kennedy Project for the development of the concept of public value and (b) the need of managers of an account of the value produced by their organization, which needs not only a story but also a proven accomplishment of what has been concretely done. In other words, in the value production process, there should be a story (or an account) of the aims pursued by the organization.

Public value can finally be considered as *performance*, that is, as a performance measurement tool. This is the approach of Kelly et al. (2002), according to which public value is “the value created by government through services, laws, regulations and other actions” (Alford and O’Flynn 2009, p. 184).

Summary

For a long time, the concept of “value” was applied to public administrations on the basis of assumptions similar to those that characterize private for-profit organizations, mainly using economic, financial, and equity indicators. The atypical exchange mechanism of public administration (and, in general, of not-for profit organizations) makes it difficult to assign a monetary value to the services that these organizations provide. The concept of value cannot focus exclusively on shareholders; in all types of organizations, and especially in public administrations, it must be observed from a multi-dimensional perspective. In these organizations it can be understood as the qualitative and quantitative degree of satisfying the needs of individual citizens and/or the administered community. Therefore, its measurement cannot be limited to the monetary meter. In brief, public value postulates:

- The achievement of the organization's institutional objectives
- The conformity of the results achieved not only to the objectives defined at the planning level but also to the expectations of the community
- The use of available resources avoiding their waste (i.e., their efficient use)

Quality Empowerment

Jie J. Zhang
Gustavson School of Business, University of
Victoria, Victoria, BC, Canada

Synonyms

[Employee empowerment](#); [Employee involvement](#); [Participatory management](#); [Quality delegation](#)

Description

Quality empowerment (QE) is an integral part of total quality management (Lawler 1994). QE focuses on increasing employees' responsibilities and/or authority, which contrasts it with the traditional top-down, command and control management model. A quality-empowering model of management promotes employee ownership and leadership, involves employees in planning, distributes information, encourages

learning and growth, and ultimately achieves high-quality output and customer satisfaction. The effective use of QE can therefore enhance a company's internal culture, brand reputation, and financial success by distributing power, information, knowledge, and rewards throughout the organization. QE has many additional benefits for both the organization and the employee, including increased trust and motivation, decreased employee turnover, and greater innovations. The philosophy underlying QE can contribute to sustainable development as it can shrink power imbalances, support democratic decision-making, stimulate innovations crucial to solving wicked problems (Buchanan 1992), and strengthen society while reducing negative impact on the environment.

QE may also be called "employee empowerment." It is also sometimes referred to as "employee involvement," "quality delegation," and "participatory management." Although these terms are often used interchangeably, QE maintains a special focus on quality and conveys additional meaning inherent to the word "empowerment." "Empowerment" absorbs the terms involvement, enrichment, enlargement, and delegation but also expands to include "alternative intrinsic and/or extrinsic employee involvement practices ... increases the scope of employee decision making responsibility and authority provided" (Dimitrades 2001, p. 20).

Introduction

Empowering employees is considered the cornerstone of total quality management systems (Ripley and Ripley 1992). Quality systems could trace its roots back to the medieval Europe (American Society for Quality 2019). However, some of these systems, such as the Factory and Taylor systems, could have a negative effect on employee empowerment as they emphasized control and inspection and risked reducing the employees' sense of "autonomy in the workplace" (American Society for Quality 2019) or limited employee well-being in other ways. In the mid-twentieth century, Japanese manufacturers implemented the new "total quality" approach, which improved all elements of organizational processes, including human resource and quality management. Later US adopted this model, named it total quality management (TQM), and created new awards, systems, and designations. Effective TQM programs have been shown to improve operating performance and stock price performance (Hendricks and Singhal 1997, 2001).

Following the human relations movement of the 1950s and 1960s, quality empowerment emerged as a key principle of TQM because "the greatest motivation and the greatest number of good decisions come when people are free to make their own decisions — at least where their own workspace or environment is concerned" (Ripley and Ripley 1992, p. 28). To further motivate and cultivate employees' achievement in a work setting, management began job enrichment to give employees additional responsibilities that would have previously only been carried out at higher levels of the organization, as well as job enlargement to increase the horizontal scope of a workers' job (American Society for Quality 2019). The TQM tool "quality circles" where employee volunteers meet regularly to solve problems in their work area is an example of how effective empowerment and teamwork contribute to quality and productivity, thus marking a core value shift from quality inspecting to building

quality (Lawler and Mohrman 1985; Ripley and Ripley 1992).

QE's direct influence on employee motivation and subsequently their self-efficacy make it an important tool in sustainable management (Hostager et al. 1998). As a growing number of companies have adopted sustainability initiatives, the role of individual employees in implementing those policies becomes ever more important (Lamm et al. 2015). For example, individual employee's motivation has been proposed as a primary driver to their engagement in organizational ecoinitiatives (Ramus and Killmer 2007).

The Practices of Quality Empowerment

The concept of empowerment continues to evolve since the human relations management movement started in the first half of the twentieth century. In the 1960s–1970s, empowerment focus was on power sharing or workplace democratization. In the 1970s–1980s, the focus shifted to enabling human welfare through increasing self-worth, knowledge, dignity, and respect. Evidence showed that productivity and worker empowerment were both compatible and mutually reinforcing (Ripley and Ripley 1992). In the 1980s–1990s, empowerment emerged as a way to promote quality and productivity by encouraging employee participation in decision-making. Suggestion programs such as "quality circle" were widely adopted (Lawler and Mohrman 1985). They collect ideas from people closest to the work and encourage participative decision-making, which increases a sense of ownership, accountability, and teamwork, as well as increasing the commitment of employees across the organization to quality, all resulting in a culture of continuous improvement. This approach to empowerment arguably had the most effect on TQM, as visionary leaders realized the strategic significance of having empowered employees: it can result in better decision making and higher levels of training, motivation, and productivity. Such QE programs prevent problems by

encouraging certain “behaviors, attitudes, and controls” that are effective to managing product or service quality in the workplace. QE therefore has the potential to improve a firm’s financial performance, response to customers, and competitive advantage.

Applying the Philosophy of Quality Empowerment to Sustainable Development

The UN World Commission Report on Environment and Development (also known as the “Brundtland Report”) defined “sustainable development” as meeting the needs and aspirations of the present generation without compromising the ability of future generations to meet their needs (Brundtland 1987b). The Brundtland Report called for international action to meet the common challenges ranging from ozone depletion to biological diversity to equality, which are issues that transcend nationality, culture, ideology, and race. Sustainable development represents “a form of progress for social and economic development that enhances the resource-base rather than degrades it. It requires a more equitable distribution of wealth than currently prevails within and among nations, and it aims at the eradication of global mass-poverty, keeping options open for the future” (Brundtland 1987a, p. 292).

The primary approach driven by a QE philosophy – distribute power, information, knowledge, and rewards – can be applied to promoting sustainable development and help solve or lessen complex, global problems such as the ones noted above. At the individual level, empowered employees enjoy more autonomy in their work and problem-solving and stronger support to develop their skills and talents to produce better results (Dahlggaard-Park 2015). As a result, organizations may experience more efficient and/or innovative problem-solving and increased competitiveness due to higher quality. Better product quality management can also have a positive impact on the environment, as in the case of an

empowered employee who identifies and eliminates unnecessary waste in her work. Along the same vein, solving global mass poverty also requires empowerment that focuses on increasing poor people’s freedom of choice and action to shape their own lives (Rayan 2002).

The threats to human survival are common in that their effects often occur far from their sources – that often the people who suffer their consequences do not benefit from the activities (Brundtland 1987a). The flatter organization structure found in an empowered organization (American Society for Quality 2019) can potentially mitigate “the [improper] distribution of power ... [that] lies at the heart of most environment and development challenges.” Empowered organizations challenge traditional power structure by institutionalizing a new one where visionary leaders listen to and support employees for learning and growth, therefore enhancing the well-being of the employees, their family, and communities. A QE philosophy recognizes and improves the positions of the disadvantaged, thus contributing to the unity of human needs by creating a functioning multilateral system that recognizes that “the world is one” with the premise that all humans have fundamental rights (Brundtland 1987b). Empowerment thus has the potential to affect wicked problems on a global scale.

Summary

Quality empowerment has the potential to evolve from a strategic human resource management approach to one that develops and draws on the talent of all humans. The primary approach of QE focuses on increasing the independence, scope of duties, and decision-making capacity of people closest to the issue. Visionary leaders can apply this approach to create a structure where individuals can realize their potential in their roles and commit to continuous improvement and innovations. This results in an enhanced sense of control and well-being that sustains more equitable social and economic development.

Quality Management

Ana Horvat

Department of Quality Management and Standardization, Faculty of Organizational Sciences, University of Belgrade, Belgrade, Serbia

Definition/Description

In the 1950s and 1960s, pioneers of quality management such as W. Edwards Deming, Joseph M. Juran, and Philip Crosby contributed to building early models and frameworks, of which most notable are Deming's 14 points, Crosby's Zero defects, and Juran's Quality Trilogy, for helping the organizations to implement "good quality management" (Oakland 2003). These early approaches were used as fundamentals for developing quality management models in the 1980s and 1990s as Total Quality Management (TQM), ISO 9000, PDCA, and Six Sigma Process Management (Hoyle 2007) and business excellence models and awards (Sousa 2003). Throughout the evolution of quality management thinking, there is movement from the quality of products and services and related processes, throughout business outputs and all processes, to TQM and quality assurance (Hoyle 2007). In ISO 9000, quality management is defined as "coordinated activities to direct and control an organization with regard to quality." These activities are quality planning, quality improvement, quality control, and quality assurance (ISO 2015a). In ISO 9000:2015, quality planning is defined as "part of quality management focused on setting quality objectives and specifying necessary operational processes, and related resources to achieve the quality objectives," quality control as "part of quality management focused on fulfilling quality requirements," quality improvement as "part of quality management focused on increasing the ability to fulfill quality requirements," and quality assurance as "part of quality management focused on providing confidence that quality requirements will be fulfilled."

The Concept of TQM

The process toward achieving quality can be organized in few stages, inspection, statistical quality control, and quality assurance with the wider management issues of planning, control, and organization (Garvin 1988). These stages were followed by the development of the concept of TQM. The TQM, as we understand it today, was developed through the 1980s and contained the major features for policies, directions, and strategies of organization captured in a basic TQM model (Oakland 2003). Major components of this basic framework were quality circles (teams), processes associated with customer relations, and processes related to suppliers as the essence of this model, tools regarding statistical process control and problem-solving, and quality systems such as ISO 9000, linked through culture, communication, and commitment (Oakland 2003). From this early framework, the culture, communication, and commitment were integrated into a new framework for TQM in which processes are “a key linkage between the enablers of planning (leadership driving policy and strategy, partnership and resources), through people into the performance (measured by people, society, customers, and key outcome)” (Oakland 2003). Research carried out by Qasrawi and coauthors (2017) suggests that TQM practices lead to the improvement of organizational performance. Hoyle (2007) stated that “all the principles, methodologies, tools, and techniques in the field of quality management serve one purpose, that of enabling organizations to close the gap between the standard required and the standard reached.”

Quality Management Principles

ISO 9000:2015 focuses on seven quality management principles Customer focus, Leadership, Engagement of people, Process approach, Improvement, Evidence-based decision making, and Relationship management. The customer focus principle involves attracting and retaining

“the confidence of customers and other relevant interested parties” (ISO 2015a). Meeting customer demands and exceeding customer expectations are managed through links between customer and business processes (Sousa 2003) to create more value for the customers. Leaders tend to create an environment in which employees are motivated to achieving the objectives of the organization. Oakland (2003) stated that effective leadership and total quality management applied together “result in the company or organization doing the right things,” so leaders are important for business success. Engagement of employees is important to utilize the effectiveness and efficiency of an organization and leads to the increased capability of the organization to create and deliver value (ISO 2015a). In standard ISO 9000:2015, process approach principle is defined as follows: “Consistent and predictable results are achieved more effectively and efficiently when activities are understood and managed as interrelated processes that function as a coherent system.” Deming’s PDCA cycle is incorporated in the process approach employed in quality management systems standards such as ISO 9000. This cycle can be defined as follows: “Plan: establish the objectives of the system and its processes, and the resources needed to deliver results in accordance with customers’ requirements and the organization’s policies, and identify and address risks and opportunities; — Do: implement what was planned; — Check: monitor and (where applicable) measure processes and the resulting products and services against policies, objectives, requirements and planned activities, and report the results; — Act: take actions to improve performance as necessary” (ISO 2015a, b). Further, according to the standard ISO 9000:2015, improvement is defined as “essential for an organization to maintain current levels of performance, to react to changes in its internal and external conditions, and to create new opportunities.” Decisions based on evidence lead to increased reliability and objectivity in achieving desired results (ISO 2015a), and according to ISO 9000, sustained success is more likely to be achieved if organizations manage their relationships with all of its interested parties.

Quality Management System

In the late 1990s, the focus of the companies moved from the quality of products and services to incorporating quality in business processes through ISO standards certifications (van der Wiele and Brown 2002). ISO 9001 is a generic standard for quality management systems, which makes a significant improvement to a company's performance. According to ISO 9000:2015, quality management system is "part of a management system with regard to quality" and management system is defined as follows: "set of interrelated or interacting elements of an organization to establish policies and objectives, and processes to achieve those objectives." The requirements of ISO 9001 are quality management system requirements. Liebesman (2008) suggests that the adoption of ISO 9001 requirements increases various outputs such as customer satisfaction, revenue recognition, and information security. Saraiva and Duarte (2003) emphasized the social and economic implications as an important motive for the increased ISO 9001 implementation globally. Quality management systems need to be designed in a sense that all components fit together and "work together to achieve a common purpose," and it covers all the functions and activities of the organization that contribute to this purpose (Hoyle 2007).

Quality Management Tools and Techniques

There are techniques and tools which focus on a particular aspect of quality management are process flowcharting, cause and effect analysis, advance product quality planning, statistical process control (SPC), quality costs, just-in-time, quality circles, six sigma, design of experiments (DOE), measurement systems analysis (MSA), 8D, and risk assessment techniques such as failure mode and effects analysis (FMEA), and hazard analysis and critical control points (HACCP) (Hoyle 2007; Oakland 2003). These quality management tools and techniques are widely

employed in various organizations as elements of a quality management system that provide better organizational performance.

Summary

During the 1950s and 1960s, gurus of quality management such as W. Edwards Deming, Joseph M. Juran, and Philip Crosby had built principles and frameworks upon today's quality management is based on. These early approaches lead to further development of quality management, which were used as a fundamental basis for developing new models in the 1980s and 1990s, of which the most notable are: TQM, ISO 9000, PDCA, six sigma process management, and business excellence models and awards. Within understanding and developing basic concepts of quality management thinking, the initiative was made to move from the quality of products and services towards TQM and quality assurance. The TQM, as it had been developed during the mid- to late 1980s had incorporated the major features for quality management practices of organization captured in a basic TQM model, followed by moving the focus from the quality of products and services towards incorporating the quality business in ISO standards certification in the late 1990s. The evolution of quality management underlines the relevance of all the practices in the area of quality management to enable "organizations to close the gap between the standard required and the standard reached" (Hoyle 2007). Quality management is defined in ISO 9000:2015 as "coordinated activities to direct and control an organization with regard to quality." These activities are identified as quality planning, quality control, quality improvement, and quality assurance (ISO 2015a). According to the same standard, there are seven quality management principles: customer focus, leadership, engagement of people, process approach, improvement, evidence-based decision making, and relationship management, whose application gives the organization the capacity to respond to the demands of a changing environment.

Quantification of Business Ethics

Alexander Kriebitz and Raphael Max
Technical University of Munich, Munich,
Germany

Synonyms

[Comparability of business ethics](#); [Measurable objectification of business ethics](#); [Measurement of business ethics](#)

Definition

Quantification of ethics implies that data input is used for an ethical judgment of a particular organization or in some cases even of individual persons. In the last couple of years, the debate on quantification of business ethics has gained prominence in the academic and practical discourse, given the increased use of key performance indicators (KPIs) to evaluate the ethical performance of organizations. This tendency goes along with an increased use of figures and quantification schemes, providing information on organizational ethical performance or alternative concepts found in business ethics. The implications of these schemes are highly relevant for the current sustainability discourse, as they increasingly determine whether and how much sustainability funds invest in a particular sector or company, as they influence the public perception of an enterprise and as they are increasingly relevant for compliance with ESG criteria in the supply chains of larger enterprises.

Historic Development of Quantifying Business Ethics

The notion of quantifying ethics originated in different academic and practical contexts including the measurement of normative concepts in political science expressed in indexes measuring the abundance of states to human rights and rule of law, the general tendency of quantification in the business world and the increasing use of credit ratings for companies.

In the context of business ethics, ratings pertaining to normative concepts appeared very recently starting with the first approaches of measurement of abstract concepts such as consumer sentiment in the 1952 established University of Michigan's Index of Consumer Sentiment (ICS), the Conference Board Consumer Confidence Index (CBBMI), and the American Customer Satisfaction Index. Building on this, scientists have become increasingly involved in the ethical performance of individual companies and their impact on consumer decisions. In contrast to the Corruption Perception Index or to the aforementioned measurement tools of consumer satisfaction, contemporary approaches have become more normative and less descriptive. The Business Ethics Index developed by Tsalikis and Seaton (2007) is a tool to measure ethical behavior of companies, comprised of four measurements representing the dimensions of "personal-vicarious" and "past-future", highlighting consumer sentiments toward business ethical practices. In the last years, the focus has switched from general evaluation to explicitly ethical issues. One prominent example for this development is the Good Company Index, which examines specific company behavior through three of its primary roles: how the company acts as an employer, as a seller, and as a steward of the community and environment. Although the Good Company Index partially embraces the idea of ethicality, it is more a general assessment of companies in terms of the relationship of the company with the individual stakeholders. The most widespread form of quantification schemes in business ethics can be encountered in the form of ESG ratings, measuring a company's long-term commitment to socially

responsible investments (SRI) and environmental, social, and governance (ESG) investment standards. Examples for ESG data would be ratings of MSCI ESG, ISS ESG, Sustainalytics, and Vigeo Eiris as well as standards on sustainability reporting. Therefore, the aforementioned ESG ratings have to be put in a larger context of the quantifying ethically relevant concepts and have gained momentum against the backdrop of the taxonomy debate in the European Union and recent legislation in nonfinancial disclosure (see La Torre et al. 2020). In general, we encounter a tendency of the use of key performance indicators (KPIs) in the business world and public administration, which help to standardize processes and are used to measure the profitability of a specific department or the usefulness of a specific business strategy (see Agostino and Arnaboldi 2017; Taylor 2007). Likewise, some concepts are devoted to specific topics such as diversity including the Bloomberg Gender-Equality Index or the Thomson Reuters Diversity and Inclusion Index, or climate change including the ET Carbon Rankings.

Methods of Quantifying Business Ethics

Quantifying business ethics involves collecting, processing, and presenting data. The methodology usually corresponds with the concepts represented by the rating, ranking, index, or certificate (see Diez-Cañamero et al. 2020).

Data Input and Sources

The data input in quantifying business ethics differs depending on the area observed. For the measurement of ecological aspects, primarily scientific data points are used, such as CO₂ emissions, water and energy consumption, or quantity of waste. Social aspects could be facts such as the signing of certain agreements and frameworks, the introduction of certain tools and processes such as human rights training, or the fundamental analysis of business models. Diversity can be measured by the composition of the board members or the numbers of employees with severe disabilities (Global Reporting Initiative 2021). In political science, measurement instruments such as the Freedom

House Index provide an overview of the political regime type of the observed country, by accessing raw data from a set of country-specific indicators including aspects such as centralization of power or human rights conduct. Questions addressed in the Freedom House Index include evaluation questions such as: Could all candidates make speeches, hold public meetings, and enjoy fair or proportionate media access throughout the campaign, free of intimidation? Did voting take place by secret ballot? (Freedom House 2021) Further data input can be generated from surveys and other statistical data. The Corruption Perception Index constitutes another tool of measuring an ethically relevant concept, namely, the level of corruption in a specific country and is based on surveys, which track how the local population perceives corruption (Lambsdorff 2007). The Good Company Index that is based on The ISS-oekom Corporate Rating uses primarily financial data, whereas the CK Financial Sanction Screen measures the monetary amount of fines for each company (see Diez-Cañamero et al. 2020).

Data Processing and Evaluation

The existing data are then further processed by methodologies. The data points are either taken over directly and only weighted differently in an overall concept, as in the case of scientific data, or the existence or nonexistence of a certain fact is checked using a binary variable technique, or data is classified based on the subjective opinion of an expert. The Freedom House, for instance, converts data concerning the political system into a mathematical formula. The Corruption Perception Index converts data into a score and used as an input for research or as a criterion for decision making. The main question here is how quantification schemes interpret and compare data. In some cases, the evaluation process is audited externally by an external committee or in the form of financial audits (Diez-Cañamero et al. 2020). The Good Company Ranking uses for example the assessment of experts, which are confronted with data input (see Gazdar 2006). Moreover, the Good Company derives its final scoring by aggregating the results of the dimensions of society, employees, environment, and

financial integrity (Good Company Ranking 2018).

Data Output and Presentation

The data is usually presented in the concepts of ratings, rankings, indices, or certification solutions. Ratings mean that the data used are evaluated using a methodology and, in the end, the combination of the data results in a value that can be compared with other companies or, based on its level, should already be interpretable on its own. An example would be the products of MSCI ESG, ISS ESG, Sustainalytics, and Vigeo Eiris. In rankings, entities are compared using a methodology and placed in an ordinal or cardinal order. An example of a ranking in this sense would be the Good Company Ranking. In the case of ethical certification, it is checked whether an entity or person has reached a certain predefined threshold and is consequently classified as ethical in the sense of the seal when this threshold is fulfilled. An example of this would be the German FNG certificate for sustainable financial funds.

The result of these processes varies. Some rankings and ratings culminate in normative statements such as The Times Top 50 Employers for Women or the Good Company Index or the MSCI World ESG Leaders Index, which classifies companies in AAA, AA, A, BBB, BB, B, and CCC. In political science, the Freedom House Index derives assessments of countries as “free,” “partly free,” and “unfree” (Freedom House 2021). As laid out by previous research, “the distinction between good and deviant has come to be analogous to the distinction between democracy and non-democracy” (Lidén 2014, p. 51), which is why the classification of political regime types bears implications for ethical judgments.

Critique of Quantifying of Business Ethics

The increasing tendency toward ESG ratings and other quantification schemes notwithstanding, the business ethics reflection on ESG ratings is a novel phenomenon in the business ethics discourse. Literature on ESG ratings schemes stems originally

from literature on accounting and finance. However, existent business ethics approaches and contributions from other fields of ethics (Brauneis and Goodman 2018) bear rich implications for the assessment of the current situation. This applies in specific to the epistemological role of measurement and quantification in social sciences in general (Michell 2003) and ethics in particular (Miller 2005). Typically, the debate on quantification of ethics or of ethical conduct revolves around organizations compromising a larger number of persons and not on the performance of individuals (Liang et al. 2018).

The possibility and permissibility of quantifying ethics hinges on certain assumptions on the meta-ethical level. Assumptions are here based on the general question of ethical accountability of collective organizations, the acceptance of universal principles of ethics and finally the feasibility of measuring and then quantifying ethics (see Merry 2021). The first and foremost question is whether quantification as such is possible in the context of business ethics. This concerns primarily the measurement of social indicators such as numbers and statistics on human trafficking and the debate on quantifying CO₂ emissions or environmental figures to a lesser extent (Windolph 2011). Especially, the measurement of social determinants such as wealth, poverty, or inequality is therefore the object of dispute in economics and ethics (Piketty 2014; Purdam et al. 2008; Van den Bergh 2009).

The second debate concerns the ethical permissibility of quantifying concepts such as human rights, child labor, and the idea of deriving judgment solely from the evaluation of statistical information. On the contrary, some utilitarian approaches have promoted the option to measure the ethicality of an arrangement or situation by offsetting its positive and negative consequences. Contemporary approaches endorsing quantification-based approaches to business ethics could be identified in the works of William McAskill or Peter Singer. A concrete example of a key performance indicator-based understanding of ethics is the United Nations Sustainable Development Goals, which are often translated in quantifiable concepts (Spaiser et al. 2017). Likewise,

the World Bank data concerning absolute poverty is used as a criterion for economic decisions and social policies. The idea of offsetting positive and negative consequences of corporate actions however has drawn criticism from deontological approaches, which have emphasized on the importance of actions and motives behind actions over consequences and the reliability of data. Moreover, consequentialist approaches have been accused of oversimplifying complex nature of human behavior and human interaction as well as the consequences generated by both. These two approaches produce major ramifications for the debate on quantifying ethics, owing to the fact that quantification schemes are likely to influence judgments and perceptions of economic subjects such as investors and owing to the fact that deontological approaches would be opposed of merely analyzing the consequences (such as CO₂ emissions) of corporate actions. Here, the ascribed “governance of numbers” and “fixation to metrics” have evolved as major aspects of the general critique on quantifying of ethics (Muller 2019). Along similar lines, questions arise on the normative implications of ESG ratings:

- Do ESG rating imply that a company is ethical/unethical? How is the line between compliant/incompliant drawn?
- What are the implications of cooperating/interacting/dealing with/buying from a company having a good/bad ESG rating?

Prevailing ethical theories would differ in their evaluation of both questions. From a consequentialist standpoint, it would be plausible to argue that quantification schemes make it easier to identify ESG risks for investors, who aim to stake money in projects they regard as sustainable, and that simplification will facilitate the growing pivot to sustainable finance products (see Landi and Sciarelli 2019). Deontological approaches however would warn that standardized ESG ratings could have major ramifications for the classification of companies and could lead to biases, given the specific business sectors companies are operating. Moreover, strict standards on ESG could hinder the access of companies in developing

economies to finance what would require a stronger focus on “capabilities” for the design of ESG ratings.

Apart from the more general debate on the feasibility and permissibility of ESG ratings and quantifying ethics, research has dealt with the practical concerns in implementing these measurement schemes. Several studies (Berg et al. 2019; Dimson et al. 2020; Gibson et al. 2019) have highlighted the divergence among ESG ratings, when it comes to the classification of single companies based on different approaches on how to define and then quantify the KPIs making up the respective ESG rating of a company.

A general observation here is that the complexity of concepts such as business ethics, sustainability, or ESG makes measurements more difficult and prone to biases. According to Windolph (2011), major critique points on ESG ratings and other ethical quantification schemes include the lack of standardization, the lack of transparency, biases, trade-offs, and incentive structures for rating agencies. In difference to the debate in the early 2010s (Windolph 2011), standardization of ESG topics has become more common, owing to the fact that the European Union has standardized sustainability reporting by introducing the Non-Financial Reporting Directive (2014/95/EU). Likewise, initiatives such as the Global Reporting Initiative have contributed to more and more similar reporting schemes, what includes disclosure of cases of corruption [GRI 205] and suppliers considered to have significant risk for incidents in sustainability reports [GRI 408] (Brown et al. 2009; Marimon et al. 2012). The growing tendency of standardizing ESG rating might here conflict with research pointing at biases in the design of quantification schemes. Perceptions of sustainability and the inclusion of specific topics and the noninclusion of other topics raised in the discourse often influence the way ESG ratings are set up. This is important against the backdrop of an intensive discussion within the sustainability discourse and different concepts on sustainability and ethics on an international level. Moreover, even more general framework such as the United Nations Sustainable Development Goals are concerned with

conflicting norms, for example, the perceived trade-off between ecological sustainability versus economic development (see International Council for Science 2015). Factoring in and acknowledging these inherent biases, conflicts, and limitations makes a significant difference in providing a more nuanced picture on the ethics performance of an individual company. Given the role of moral judgment of political regimes, the classification of a single country in a specific group, for instance, could further have major ramifications on the judgment of a country’s government and its comparison to others (see Guerin and Manzcchi 2009; Kriebitz and Ammah 2020).

A further aspect of critique raised in the discussion concerns the fact that the sources of ESG rating are often deemed opaque, especially in terms of the methodology that is used for deriving the ratings of a specific company (Delmas and Blass 2010).

Summary

The use of quantification schemes in ethics, in particular in form of ESG ratings, has evolved as a major tendency in the applied business ethics. Consequently, the debate on how to deal with quantification schemes and normative judgments has gained visibility. This concerns in specific the opaqueness of many ESG measurement tools and other methodological questions. The far more general questions on the assumptions of most ESG rating systems and other business ethics ratings tools is still in its infancy, though. This concerns the feasibility of classifying companies as unethical or immoral, based on a specified data input. Other discourses which are occupied with the treatment of data might be helpful. The concurrent debate on data and AI ethics bears here major ramifications for the ESG discourse, as it pinpoints to the role of biases in the selection of data sets. Given the different approaches to ESG topics and to sustainability and ethics topics in general, transparency might be crucial for understanding how a rating scheme is deriving its exact judgment. This debate connects therefore to the general questions on how to put ethical KPIs in

figures and to assess the ethical performance of companies in specific. By taking this input into consideration, ESG ratings and other ethics measurement tools could gain validity and acceptance.

[Decoupling](#); [Delinking](#); [Factor 4](#); [Growth](#); [Innovation](#); [Jevons Paradoxon](#); [Productivity](#); [R&D policy](#); [Sufficiency](#)

Description

Eco-efficiency still is the most important option for harmonizing economic growth and environmental goals, for example, as formulated in the UN SDGs 2015. Eco-efficiency increases provide the chance to continue growth of output (GDP) and to reduce input (natural resource consumption) at the same time, that is, delinking (decoupling) the two variables. If eco-efficiency increases significantly, doubling of GDP within three decades could be combined with halvening of resource inputs (“factor 4”). However, there is no empirical evidence for such high rates of eco-efficiency increase. An “efficiency revolution” would be necessary but has not materialized yet. Moreover, increases in eco-efficiency tend to reduce cost of production and prices of products – hence stimulate output and

resource consumption. This expansive effect is called “rebound effect.” It has been analyzed already in 1866 by W. St. Jevons (the Coal Question). Empirical studies today find significant rebound effects, often between 25% and 100%. The larger it is, the less can eco-efficiency contribute to sustainable development (reduction) goals. Eco-efficiency increases and their expansive effect are the fundament of “green growth.” Eco-efficiency stimulates the economy and increases growth rates. This is good for jobs and incomes but not for the environmental impact. The rebound effect can be reduced if eco-efficiency increase is combined with quantity (caps) or price (tax) measures. However, the rebound effect reduces the practical relevance of eco-efficiency increases. Sustainability policy should therefore not only be based on efficiency but has to consider the second option, sufficiency, too.

Eco-efficiency and Sustainable Development

Increase of eco-efficiency is the dominating answer to almost all challenges in the context of sustainable development. The basic idea is simple: Environmental impact I (pollution) depends on two components: the size of GDP and the pollution (resource consumption) which is necessary to produce one unit of GDP:

$$I = I/GDP * GDP$$

I/GDP is a measure of “eco-efficiency.” Increasing eco-efficiency means reduction of pollution per unit of output. This could also be formulated in terms of productivity as GDP/I . The challenge then is to increase eco-productivity, the output per unit of pollution.

If I/GDP would be constant, the consequence of economic growth would be a proportional growth of I . If eco-efficiency increases, it is possible to delink economic growth and pollution, improving environmental quality without lowering the standard of living (GDP).

If, for example, over a period of 20–30 years eco-efficiency (productivity) would quadruple

(“factor 4”, see Weizsäcker et al. 1997), GDP could double (grow at 2–3% p.a.) and yet I could be reduced by 50% (= delinking).

$$I = I/GDP * GDP$$

$$\frac{1}{2} = \frac{1}{4} * 2$$

This would require an increase of eco-efficiency of 4–5% p.a., that is, an “efficiency revolution.” Climate policy goal in Germany is to reduce CO₂-emissions by 80–95% in the period 1990–2050, that is, up to “Factor 20.” This requires an increase of CO₂-efficiency of 3% p.a. (80% goal) or even more ambitious 5% p.a. (95% goal). In fact, for example, energy efficiency increases by (only) 1–2% p.a. in the OECD countries (e.g. Parrique et al. 2019; UNEP 2019; IEA 2020). An “efficiency revolution” would be needed – but is not (yet) taking place. Rebound effects can provide one explanation for this lack of success.

Rebound Effects (RE)

The phenomenon is simple and omnipresent: (Binswanger 2001; Santarius 2012; Sorrell & Dimitropoulos 2008): If a product gets more efficient, that is, less resource consuming and hence less costly to operate, this creates an incentive to buy and use more of it. Resources could be labor or natural resources.

The most famous historical case has been analyzed by W. St. Jevons (1866), the Coal Question: “It is wholly a confusion of ideas to suppose that the economical use of fuel is equivalent to a diminished consumption. The very contrary is the truth. New modes of economy will lead to an increase of consumption.” The explanation is: “If the quantity of coal used for blast-furnance be diminished in comparison with yield, the profits will increase, price will fall, demand increase . . . (over-)compensate the initial reduction of coal consumption.” This has been called the Jevons Paradoxon: Increase in resource efficiency may result in an increase rather than a decrease of total resource

consumption. Today, there are many more examples:

- While energy efficiency of machines and consumer goods (refrigerator, heating, etc.) increases, overall energy consumption does not decline.
- With more efficient light technology (LEDs) nobody is bothering about turning out the light.
- More fuel efficient car engines encourage higher powered cars (SUVs), driving more and longer distances.
- With better insulation of buildings, heating costs decline, higher room temperature is “affordable,” not necessary to wear a sweater any more.

The overall “message” of the Jevons Paradoxon is a warning, not to overestimate what technology can do for a reduction of (natural) resource consumption.

Analytical Foundations and Empirical Evidence

RE are identified by comparing two cases: What would be the effect of an efficiency increase on the quantity of demand (e.g., energy demand) if price remains constant (i.e., *ceteris paribus* analysis)? Energy demand would then be constant and the higher efficiency would completely reduce overall energy consumption. This hypothetical case is compared with the more realistic case that price declines due to more efficient (cost reducing) technology. The delta is the “rebound effect.”

If fuel consumption of cars declines from 7 l/100 km to 6.3, this is a 10% increase of fuel efficiency – and the expectation would be that total fuel consumption (and CO₂-emissions) will also decline by 10%. If the decline is only 5% (1%), there is a rebound effect of 50% (90%). The “gap” of five percentage points is the result of higher demand for fuel (more and longer rides, faster driving, etc.). Half of the efficiency increase is lost, “consumed” by users. If there is no reduction at all (0%), the rebound effect is 100% (full rebound). If there is actually an increase in

demand, this would be called “backfire” (addressed by Jevons 1866).

Efficiency increase has direct and indirect effects and empirical results depend on the scope of analysis. Focus of RE analysis is on direct, sector-specific effect of a more eco-efficient technology on lower costs and prices and higher demand (e.g., more fuel efficient cars, demand for fuels). However, price reductions also have an income effect, that is, lower price is equal to higher (real) income. The savings from the fuel efficient car could also be used for an (additional) flight and hence would not be reflected in the demand for car fuel – an underestimation of the rebound effect. In more general macroeconomic terms: Eco-efficient technologies have the potential to stimulate overall GDP-growth (“green growth”) which is related to all kinds of additional natural resource consumption (macrorebound). The new technology also comes with its inherent eco-impacts, for example, e-cars depend on critical resources for batteries; more efficient buildings “consume” (additional) insulation material. These effects throughout the (global) supply-chain would have to be included in a complete analysis of RE.

Increases in eco-efficiency are part of the economic innovation process. They are typically the result of cost-intensive R&D activities and innovators will try to charge a high price to cover these costs and to earn an (extra-ordinary) profit as a reward for their successful search efforts. It depends on their monopoly power whether the eco-efficient technology comes with low(er) prices and hence how fast the eco-efficient technology diffuses beyond the niche market. Monopoly power could be a restriction on diffusion and hence on rebound effects, at least a temporary effect until barriers to market entry erode. In fact already Jevons’ coal question highlights an innovation process: a more efficient steam engine, now attractive for new uses throughout the economy (diffusion); this is the basic reason for higher (coal) demand, not so much the increased demand of incumbents.

The explanation of RE can be based on standard microeconomics and rational decision making only: lower cost (total cost of ownership)

increase demand. Behavioral (economics) aspects beyond rational decision making can add some aspects:

- People tend to forget the initial (high) investment cost and make everyday decisions based on marginal cost: the additional cost of the “extra mile” with an efficient diesel car then is calculated as $5 \text{ l} = 6 \text{ €/100 km}$ (when it actually is 0.30 €/km, that is, 30 €/100 km).
- People “reward” themselves for doing something eco-friendly (moral licensing). Shoppers who bring their own bags to the supermarket tend to buy more sweets, crisps, ice cream, etc. Households which succeed in reducing their water consumption tend to increase their electricity consumption (see Karmarkar and Bollinger 2014).

Policies for Coping with Rebound Effects

Increase Eco-efficiency Growth Rate

If RE reduce the environmental effect of eco-efficiency improvements, one policy reaction could be to go for higher eco-efficiency growth rates, outpacing the growth of demand. The question then is how to stimulate eco-efficiency, what tools and measures are available? The challenge is to stimulate innovation activity and to change it into an eco-efficient direction. In general government has to organize a public debate on “the future we want” to change investors’ expectations and hence their strategies and search activities. The set of instruments includes:

- Government R&D expenditures (from basic research to market entry and diffusion) for “green” technologies and market segments (e.g., wind and solar energy).
- Financial incentives (e.g., favorable depreciation rules) to make investments more attractive (profitable).
- Price signal (e.g., taxing negative external effects).
- Technology forcing by regulations (e.g., ambitious fuel-efficiency fleet standards).

- Redirect science system in general (see WBGU 2011).

Control Price Reductions and/or Demand

RE can be directly addressed and reduced if either the cost and price reductions are eliminated or the potential expansion of quantity demand is restricted.

To eliminate the decline of prices, a (eco-)tax could be introduced – with tax rates increasing with the rate of eco-efficiency growth (and tax revenue spend for eco or social goals). This could be, for example, a CO₂-tax with eco-bonus. The same function could be fulfilled if real incomes could be reduced when people work less and enjoy more leisure time (reduction of working hours).

Most effective would be quantitative restrictions (caps). More efficient (cheaper) fishing technology could cause a decline of fish population. Fishing quotas could avoid this. Another example is the EU-ETS which defines reductions of CO₂-emissions (in tons) – no matter what eco-efficiency does; efficiency increases are crucial for the price of certificates, that is, the cost for companies and society. Other regulations include, for example, in the mobility sector limitation of cars “horsepower” and/or speed limits (so that it makes less sense to buy high-powered cars). Parking restrictions for SUVs instead of additional (larger) SUV parking lots and/or general reduction of parking space. In general this is the aspect of sufficiency in the sustainable development debate: how much is “enough,” promoted not only by government regulation but also by social debate and pressure (Kurz 2019).

Summary and Perspectives

Eco-efficiency is not an easy, comfortable path to SD. The potential of an efficiency revolution has been overestimated due to the neglect of rebound effects. Efficiency increases are not enough to achieve sustainability goals in growing economies. Increasing efficiency (technological progress, eco-innovation) does not guarantee SD.

Nobody is able to predict whether this gap can be closed by eco-innovation policy – given that this policy is expected to stimulate growth (rebound effect). Rebound effects are not just limited caveat against technological solutions of eco-problems, reducing their effectiveness by 20–30% of what would be “ideally” possible. The debate on RE is a reminder that technological solutions are not enough for SD and could support the unwillingness to think deeper and to change more fundamentally.

The major political consequences for the SD debate are that the wide-spread preference for technological (efficiency) solutions is – either naively or willingly – neglecting a relevant “side-effect.” There are policy options to reduce this effect but these are neither popular nor easy to enforce. When the efficiency revolution loses some of its glamour, sufficiency gains attractiveness.

No doubt, efficiency revolution and eco-innovation play a vital role in handling “hot spots” of environmental degradation. Urgent problems are reduced and shifted on what seems to be less risky fields, for example, nuclear and fossil substituted by renewable energy – seemed to be without any cost (sun is sending no bill). Eventually it turns out that old risks have been traded against new ones – often not less serious (in e-mobility the problem of resource consumption, e.g., rare earth like lithium and cobalt). With ingenuity a given planet will deliver always larger quantities of goods with less harmful side-effects. This general efficiency or modernization promise turns out to be flawed (Kurz 2015). New technologies can buy time and help to shift problems into a less risky direction – before they pop up again and require new technological solutions. Therefore, rebound is a reminder that efficiency and technology cannot be the ultimate solution, only a tool for crisis management.

Nevertheless, technology can buy time, shift the problem – but it will return, directly (coal) or indirectly (increased consumption of other goods). Technology is not a causal therapy – however, it is comfortable for (almost) everyone, as consumers do not have to change their behavior, politicians do not have to make unpopular

proposals and decisions, and companies find new markets (green growth). The more fundamental issue of sufficiency (limits of consumerism) is much harder to address.

With an increasing awareness and support for SDGs, emphasis will have to shift away from the technology race to the perception that the “future we want” is not (only) a (re)engineering job but a fundamental reorientation of human and economic development, a cultural revolution.

Definition

The comprehension of the role covered by regulation in corporate social responsibility (CSR) practices is a complex phenomenon due to a high degree of debate between academics regarding its effects. This complexity increased during the last year due to the proliferation of new forms of regulation about various topics such as non-financial reporting, GHG emissions, and sustainable corporate governance. However, despite the positive impacts of the introduction of sustainable rules, many academics agree about the existence of limitations related to the adoption of sustainable behaviors on a mandatory basis.

The Epistemology of the Concept of Regulation

The word “*regulation*” derives from the Latin *regere* that means “conduct.” According to this evidence, we have observed several attempts to favor the transition from traditional to more sustainable paradigms during the last years. In this sense, despite a large part of the CSR definition required a voluntary approach by the subjects (Dahlsrud 2008), the current scenario is characterized by several rules about mandatory CSR.

This paradigm shift has been driven by the different approaches proposed by worldwide regulators and policymakers about CSR. Specifically, during the last years, we have observed a passage from a voluntary approach to a mandatory one within some of the most common definitions of CSR proposed. A possible paradigm of analysis is represented by the conjoint analysis of some documents published by European Commission, WBCSD, and more recently, from the United Nations. Specifically, the European Commission (2001) defined CSR as “*a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis*” while the WBCSD (1999) proposed a definition of CSR who consists in “*the continuing*

commitment by business to behave ethically and contribute to economic development while improving the quality of life of the workforce and their families as well as of the local community and society at large.” On the other hand, recently, the United Nations has published the Agenda 2030 which required the Member States within the SDGs 12.6 to “*encourage companies, especially large and transnational companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle.*”

The nonfinancial reporting practices represent one of the main fields characterized by mandatory CSR. In this sense, an increasing number of academics have started to analyze these new forms of regulation. However, many of these studies have confirmed the need to increase CSR awareness through tools not based on mandatory provisions. Specifically, a large part of these studies has regarded the effects related to the introduction of the Directive 2014/95/EU in Europe and the King Code III in South Africa.

The studies performed on Directive 2014/95/EU highlighted several criticisms that negatively impacted nonfinancial reporting harmonization (La Torre et al. 2018). These studies confirmed some of the main criticisms underlined by stakeholders during the preliminary consultation about the Directive 2014/95/EU (Monciardini 2016). In fact, the firsts studies conducted about its effects showed the existence of several criticisms, such as the lack of comparability between nonfinancial reports, the abuse of unethical mechanisms such as greenwashing, and a low degree of integration of sustainable practices within the business models (Doni et al. 2019; Pizzi et al. 2020). In this sense, after 5 years since its implementation, the European Commission launched a new consultation in order to revise its contents (Venturelli et al. 2020).

The Directive 2014/95/EU criticisms confirmed as evidenced by academics that have studied other jurisdictions. In particular, many academics paid specific attention to South Africa, which represents one of the first countries to introduce within their legal systems

explicit requirements in terms of nonfinancial reporting practices through the King Code III (Adams 2017). Regarding the specific criticisms of the King Code III, some studies have highlighted how firms often adopt a “tick box approach” to comply with the legal requirements without an intrinsic orientation toward sustainable and ethical principles (Ackers and Eccles 2015). In this sense, this evidence suggests how an effective transition to more sustainable business models needs a cultural change from preparers (Bebbington and Larrinaga 2014).

Summary

Like the financial practices, recent years have been characterized by an increasing degree of regulation about nonfinancial practices. These changes have been driven by the worldwide community’s increasing attention to new topics such as the mitigation of the negative effects related to climate change and the role of women within society. The first evidence collected by academics about these phenomena has revealed how firms’ approaches to nonfinancial practices are characterized by criticism related to a possible “tick-box approach” risk. In this sense, the effects related to nonfinancial regulation in some sectors remain low. However, the regulation of practices such as GHG emissions and human rights has positively impacted worldwide sustainable development. According to this evidence, the regulation activity is characterized by a high degree of complexity for policymakers. In this sense, future research could be addressed to identify new potential areas of investigation to identify new regulation strategies.

Definition

In the world we live in, human survival and satisfaction of wants are hinged on the utilization of resources, which most times occur naturally within our environment. These are referred to as natural resources and can be distinctively classified as nonrenewable and renewable resources (Grafton 2005). Nonrenewable resources are formed over long geological periods with an

extremely low formation rate; examples include coal, petroleum, natural gas, and metallic minerals. Due to low formation rate, these materials cannot be replenished once depleted; except for metallic minerals that can be reused through recycling. On the other hand, renewable resources are usually unlimited in nature, self-replenishing over a cyclic period of time, and cannot be entirely depleted. They are replenished easily at a rate that is almost equal or faster than the rate being used by humans. These resources are continuously available for usage, and rarely affected by human consumption because of their regenerating life cycle, notable examples include sun, wind, water, geothermal, soil, biomass, and the capacity of the ecosystems to assimilate and degrade waste (Miller and Spoolman 2015).

Nearly half of the world's population is directly dependent on renewable natural resources for its livelihood; around 2.5 billion people live directly from agriculture – farming crops and livestock, while 1.6 billion people rely on forest resources for all or part of their livelihoods. In addition, 150 million people count wildlife as a valuable livelihood source, and 560 million derive all or part of their livelihood from fishing and/or aquaculture (UNEP 2012). It must however be noted that renewable resources are seldom perfectly renewable; due to the fact that all can be overused to the point where they are irreversibly damaged and as such cannot be further replenished, leading to the term “unsustainable use” (Beltratti et al. 1998). Various human activities such as urban sprawl, cultivation, irrigation, grazing, deforestation, fishing, hunting, and habitat destruction can all be causes of the destruction of an otherwise renewable resource. To therefore achieve the sustainable use of these renewable resources, a long-term management approach that enhances optimal exploitation of resources with zero environmental degradation has been voted for as the way forward (Gritsevskiy 2016).

Types of Renewable Resource

Water

Water is a vital resource required for all day-to-day human activities, and it is constantly

replenished by the water cycle; the earth is made-up of 70% water, of which less than 2.5% is fresh water (Abolhosseini et al. 2014). The larger percent of this fresh water is locked in the form of ice caps and glaciers. Only one-third of fresh water is available for human use, which could be for domestic or industrial purposes. World over, agriculture accounts for 70% of all water consumption, compared to 20% for industry and 10% for domestic use (Lindkvist et al. 2017). Water as a natural resource is pivotal to the generation of hydropower, which is the most common and largest renewable means of generating electricity for human and industrial consumption (Kothari et al. 2011). Hydroelectric power plants capture the energy of falling water to generate electricity; these plants are usually situated on or near a large water body (Fig. 1). The volume and elevation of water height determines the amount of energy that can be derived from fast-moving water from the gate of a dam on a big river. The high kinetic energy of the fast-moving water is then used to turn the blades in a turbine, which spins a generator that generates electricity. Hydropower is a safer means of power generation because it produces the least solid waste and emits no carbon dioxide into the atmosphere, maintaining a balance in the arboreal habitat (U.S. Energy Information Administration 2019).

Wind

Wind is produced by the uneven heating of the Earth. The air above the land is heated up at a faster rate compared to the air over water during the day. The heated air expands and becomes lighter, thereby making it to rise in the atmosphere, while the cooler air from the water surface blows and replaces it, thereby creating air stream (wind). It is harnessed by converting it into a more useful form of energy such as electrical and mechanical energy (Kothari et al. 2011). A wind turbine converts the kinetic energy of the wind into mechanical energy using the aerodynamics of its blades (rotation of blades), which is then converted into electrical energy via an electric generator (Fig. 2). The kinetic energy of the wind is converted into electrical energy by the rotation of the blades of a wind turbine. The blades are mounted on a rotating shaft of an

Renewable Resource, Fig. 1 Hydropower plant (Source: Adapted from U.S. Energy Information Administration 2019)

electrical generator, which spins and generates electricity (U.S. Energy Information Administration 2019). There are two types of wind turbines, namely:

- (i) Horizontal-axis turbine
- (ii) Vertical-axis turbine

The power generated from wind turbines is used for national electrical grids or for providing electricity for grid-isolated locations. Wind energy is also used to power mechanical machines to do work such as pumping of water aeration, ventilation, or milling of grains. It is a very clean, renewable, and inexhaustible form of energy (U.S. Energy Information Administration 2019).

Solar

The sun is the fundamental source of all other sources of energy. Energy from the sun has been used for time immemorial for warmth and drying of agricultural produce. Light from the sun is a

natural resource that supports life on Earth (Lindkvis et al. 2017). The sun radiates about 3.8×10^{26} Watts of power in all the directions. Out of this, about 1.7×10^{17} Watts is received by earth. The sun is the most abundant source of energy on earth. Contemporarily, solar energy is being harnessed, using different technologies to generate thermal energy or electrical energy, which is used in the residential and commercial sectors for water heating, house (air) heating, drying, or electricity generation. The first installation of solar thermal energy equipment occurred in the Sahara Desert around 1910 (Patel 2020). Photovoltaic (PV) or solar cells are used in converting sunlight into electricity. The amount of electricity generated depends on the number of solar cells arranged together. Small PV cells can be used to power small electronics, security light, watches, calculators, while larger arrangements can be used to pump water, power communication equipment, or power a whole building with electricity. It is an extremely clean renewable form of energy, as it does not emit carbon dioxide when it is being used. It is also considered as inexhaustible

Renewable Resource,
Fig. 2 Wind turbine
(Source: Adapted from
U.S. Energy Information
Administration 2019)

(U.S. Energy Information Administration 2019) (Fig. 3).

Geothermal

Geothermal is a form of energy derived from the heat generated deep within the core of the earth. It is fueled by the radioactive decay of minerals within the core and also from the solar energy absorbed at the surface of earth. Geothermal resources are theoretically more than adequate to meet human's energy needs, but only a very small fraction may be profitably exploited (Preston 1995). Scientists have discovered that the temperature of the earth's inner core is about 10,800 degrees Fahrenheit (°F), which is as hot as the surface of the sun; temperatures in the mantle range from about 392 °F at the upper boundary

with the earth's crust to approximately 7,230 °F at the mantle-core boundary; however, the thermal efficiency of geothermal plants only ranges between 10 and 23%. Geothermal power is reliable, sustainable, and environmentally friendly. It finds widespread application in timber mills, water heating, air/house heating, and generation of electricity (Ramesh et al. 1997; Abolhosseini et al. 2014).

Biomass

Biomass refers to all organic matter existing in the biosphere, whether of plant or animal origin, as well as those materials obtained through their natural or artificial transformation; it is present in a variety of different materials: wood, sawdust, straw, seed waste, manure,

Renewable Resource, Fig. 3 Solar panels (Source: U.S. Energy Information Administration [2019](#))

paper waste, household waste, wastewater, etc. (Perea-Moreno et al. [2019](#)). It is diversified in species, properties, and ways of utilization. It also distributes more evenly on the earth than many other natural resources. The stored solar energy in biomass can be effectively utilized for the production of biorenewable energy. Contemporarily, the fluctuation and increase in the prices of fossil fuels and the adverse environmental effect of burning these fuels have resulted in a more clarion call for the development of renewable energy resource, which is being considered globally as a safer and better alternative with the capacity to reduce the emission of greenhouse gases and other air pollutants. Interestingly, biomass has over the years been used, also, as a resource material for the production of bioplastics and chemicals with minimal or zero adverse environmental impacts in relation to the production of these materials from nonrenewable resources (Peart [1999](#)).

Summary

Natural resources, both renewable and non-renewable, which most times occur naturally within our environment, are critical to human survival on earth. Renewable resources are usually unlimited in nature and are self-replenishing over a cyclic period of time and cannot be entirely depleted. This is because it is replenished easily at a rate that is almost equal to or faster than the rate of exploitation by humans such as water, soil, wind, sun, geothermal, and biomass. Water constitutes about 70% of the earth surface and is naturally replenished through the water cycle. Water is the largest and most important renewable source of electricity due to uneven heating of the earth caused by more rapid heating of the air over land relative to air over water during the day leading to air stream that forms wind. Wind is another important renewable resource that is harnessed and converted into different forms of energy such as electrical and mechanical energy.

Sun is considered the earth's most fundamental energy source naturally providing warmth and light to support life on earth. Solar energy is also harnessed to produce thermal and electrical energy.

Reporting

Liliane Cristina Segura¹ and Rute Abreu²

¹Universidade Presbiteriana Mackenzie, São Paulo, Brazil

²Instituto Politécnico da Guarda, UDI-IPG, CICF-IPCA & CISED-IPV, Guarda, Portugal

Synonyms

Accounting synthesis; Financial statements analysis; Written and digital document

Description

Reporting reduces the asymmetry of the information and allows to provide, to disclose and to disseminate the organization's information to stakeholders. The organization publishes the report after collecting accounting and financial data, transforming it into information and building

the report with financial statements and auditing assessment. Reporting is an official or unofficial act of the organization to justify the performance and economic-financial analysis, in a specific period, which allows to create knowledge and to be communicated to stakeholders that influence its decision process.

The Need of Disclosure

The need of disclosure of the accounting and financial information is crucial to communicate for capital, financial and labour markets and to the society (Hrasky and Smith 2008). The investor must have detailed information about the investment promoted by the organization and to justify the allocation of resources with growing pressure for the diversity of reporting (Holton 2005).

On one hand, according to Healy and Palepu (2001), financial reporting and disclosure are important strategies to communicate performance and governance to stakeholders. On the other hand, according to Holthausen (2009), research in the accounting literature convincingly concludes that accounting standards alone do not determine financial reporting outcomes. Indeed, the organization produces reports that are useful to stakeholders. The focus of accounting information systems, according to Beest et al. (2009), is to provide financial information with high standards of quality, in the same units, to make the decision useful to the board of the organization.

Benston (1969, p. 521) argues that the unexpected accounting data *“is the difference between the data reported and the amounts calculated as just described”*. The organization publishes a report when it needs other stakeholders to know about the situation and needs to tell them and describe it precisely. A report is to inform someone, giving transparency of some process to be evaluated. Transparency proposed by Crowther and Rayman-Bacchus (2004, p. 241) is *“the external impact of the actions of the organization can be ascertained from that organization’s report, pertinent facts are nor disguised within that report and can be seen to be a part of the process of recognition of responsibility”*.

This external impact is the focus of the Benston (1969, p. 516) discussion, because it concerns an invalid representation of reality, but with two circumstances: 1st—*“corporate officers could be dishonest—they might be misappropriating the resources of the corporation”*; 2nd—*“corporate officers could be mistaken about the value of disclosure. They might not realize that the marginal value of financial statements is greater to stockholders than is its marginal cost to the enterprise.”* In this line, the focus is on transmitting information with a clear purpose, to a specific audience. These reports may cover a wide range of topics. The purpose of reports is to communicate information that has been organized following regulation, guidelines, and a detailed process of collecting the information, researching and analysing data (Yuthas et al. 2002).

It is relevant to observe the period of the report, because it is expected to have regularity of reporting, such as annual or interim report. As Campbell et al. (2001) recognize the importance of signalization through the effectively communication of the misison and, also, its strategies to the organization’s stakeholders.

As Clatworthy and Jones (2003) research, the reporting of good or bad news should present an adequate language to transmit the correct information. It is relevant to argue that Skinner (1994) publishes reasons to voluntary disclose bad news, and it lays on the language of a specific professional trained to communicate the information from the business correctly. Indeed, Benoit (1997) argues that sometimes some negative issue, especially when it is done in the form of an official document, demands a huge investigation and to consider justifications.

Hardy and Hubbard (1976, p. 917) argue that *“accountants should be concerned about effectiveness of internal and external accounting reporting”*. The authors agree and are concerned, particularly, with the possibility that the exposure to the many aspects of effective reporting, which is received by college students, may have a bearing on subsequent deficiencies which may exist in practice.

Once the report is published, Healy and Palepu (2001) stated that, for better understanding of these reports, the household savings (investors)

lie on the financial intermediaries (regulators of capital markets and financial institutions) and information intermediaries (auditors and accounting regulators) to guarantee that the information is reliable and without errors. As a result of that, intermediaries help the investors understand the information disclosed and the investors to allocate the resources correctly.

The Report Itself

The need of information and accountability forced organizations to develop the financial accounting and to report their numbers to inform stakeholders, banks and taxation authorities about its performance and economic-financial analysis. From the organization's perspective, accounting has been structured to produce a report as a written or digital document about a subject or a topic that someone has observed, heard, done or investigated about the organization, an event or even an external situation that impacted the organization, such as a pandemic situation. This is allowed to understand Zeff's (2007, p. 290) perspective that “*‘comparability’ is a very difficult notion to understand even within a country, let alone globally*”.

Accounting has changed alongside the development of business and relations in the organization. Industrial revolution could be one of the most important changes that obliged accounting to adapt from the evaluation of owner equity to a broader tool that must inform all the stakeholders how the organization is being managed, and for this reason, this is the best way for managers to communicate with the stakeholders. In the limit, the need of a higher level of quality of the report demands that stakeholders should have information to make decisions and “*to promote the comparability as key factor of usefulness of financial information*” as Gordon and Gallery (2012, p. 11) defend. The report for the external user turned out to be the most important tool to an organization's communication with their stakeholders and to perform the accountability of the firm.

The organization must disclose information to show public the way the organization has been

managed. It is known by the Agency Theory (Jensen and Meckling 1976) that there is an agent conflict between managers and stakeholders. Reporting is the process where the organization talks to the public to promote transparency. The agency theory shows the divergence of objectives between agent and principal where moral hazards tend to happen after the contract and adverse selection may happen before and after (Akpanuko and Umoren 2018, p. 297).

In 1929, the financial crises gave the accounting profession the challenge to produce reports comparable to each organization. From this time on, principles and regulations in accounting turn out to be the best way to make sure that the report would be useful for the stakeholders. Today, report to public or private organizations or not-for-profit organizations assume different frameworks, such as the accounting report, controlled and defined by the International Accounting Standards Board (IASB) with the International Financial Reporting Standard (IFRS), the Financial Accounting Standards Board (FASB) with FASB Accounting Standards, Corporate Social Responsibility reports, for example, following the model of the Integrated Report. Consequently, the financial accounting information, according to Palliserry (2012, p. 333), “*is the product of corporate accounting and external reporting systems that measure and routinely disclose audited, quantitative data concerning the financial position and performance of the publicly held firms*”.

Report in accounting means that the organization fights for transparency on the decisions of the organization. As Erickson et al. (2011) detail, the corporate report strategies are analysed from the point of view of theories of communication. This justifies why the report not only made accounting aggregation of the financial information in the financial statements—Income Statement, Balance Sheet, Statement of Cash flow—but also all the information that must be disclosed with this accounting information like footnotes and auditing report.

The quality of the report is important for two reasons: stakeholders need to understand the information correctly and they must trust in the information presented. The quality level of

the report is related with comprehension of the information and the trust of stakeholders. Five dimensions of quality were selected for assessment (comparability, disaggregation, interpretability, presentation, and timeliness) (Hodge 2012). They way the organization report its numbers are analysed by the users of information to understand how company's decision has been done and to understand other issues regarding the company's environment. Quality of reporting, relations of reporting by organization and stock prices, CSR report and the information given by this report to the users are some examples of research in this field. Organizations that have a high-quality level of report should present less information asymmetry and, consequently, should present less transaction costs with their stakeholders. In a digital world, with bigdata, artificial intelligence and completely connected with fast-run decisions, the accounting report providing timeless and accuracy is crucial to decision-makers rely on the correct information.

Regulation

The regulation focus on reporting has been increasing all over the world. However, in relation with reporting exist guidelines, as Hardy and Hubbard (1976, pp. 918–919) identify: “1. Reports should be relevant to user needs and responsibilities; 2. Reports should be on a personal level; 3. Reports should include supportive comments; 4. Reports should be consistence; 5. Reports should be timely and regular.”

The regulation of the IASB about the financial report for external users is developed with the objective to be comparable between organizations. Thus, the Conceptual Framework (IASB 2018) defines the main elements of the financial reporting. The purpose is to assist the IASB with the IFRS Standards; to develop accounting policies in order to apply these standards to transactions or events; and to help stakeholders to understand standards.

On the Conceptual Framework of IASB (2018, p. A19), the objective of financial reporting is “to provide financial information about the reporting

entity that is useful to existing and potential investors, lenders and other creditors in making decisions to providing resources to the entity”. In this sense, organizations that have negotiation with suppliers, lenders and investors should be worried to produce accounting information following this guidance. Also, given the Conceptual Framework, the general-purpose financial reporting is to show the value of the reporting organization (IASB 2018, p. A20). However, the data reported should be used to estimate the value of the organization.

The financial reporting should be used by stakeholders that look for information that will meet their needs, even though this information is not the same for each of these users (IASB 2018, p. A20). For example, the information that the lenders want to see in the financial reporting are in many cases different from the information the investors are looking for. Lenders want to see if the organization produces enough liquidity to pay their liabilities. However, the investors are seeking for the profit and the value of the business, even though the liquidity may be jeopardized. The authors agree with Trumbull (1953, p. 471) when he said: “the unsettled controversy between accountants favoring ‘all-inclusive’ income reports and those favoring ‘selective’ income reports which exclude certain special items of gain and loss cannot be fully understood”.

Another important characteristic of the financial reports is that they are based on estimates, judgments and models, as such they are not exact descriptions of the event, they are supposed to account (IASB 2018, p. A20). The Conceptual Framework establishes the rules to comply with these points. Furthermore, Schwieger (1977, p. 946) argues that it “must be able to recognize different types of accounting changes and must be knowledgeable of the proper method of accounting, the disclosure requirements and the effect on the audit opinion of each”. It can be, also, defined as a statement of event or situation when it has to do with the public services or revealed by the media.

In a summary, the financial reporting provides information about the financial position of the organization, their economic resources and claims in favour of the organization. Financial reports are also responsible to provide the information about

all the transactions and other events that changed the organization' report, showing to the investors the full concept of the operation of this organization.

Conceptual Framework also defines the qualitative characteristics of useful financial information reported (IASB 2018, pp. A25–A27). The fundamental qualitative characteristics are defined as relevance (also, materiality) and faithful representation. The financial report must be relevant, that is, capable of making difference in the users decisions. The financial information presented in the financial report is useful if it has predictive value, confirmatory value or both (IASB 2018, p. A25). Also, to be faithful the information should have three characteristics: complete, neutral and free of error (IASB 2018, p. A26).

It is a characteristic of the accounting reporting that should be comparable, verifiable, timeliness and understandable (IASB 2018, p. A73). Following these characteristics, the objective of financial reporting is providing information about assets, liabilities, equity, income and expenses. This information is useful to stakeholders for prospective future net cash inflows of the organization, assessing management's stewardship of the organization's economic resources (IASB 2018, p. A19).

The company should disclose correctly the financial information as reported by the IAS 1—Presentation of Financial Statements (IASB 2021). The objective of this standard is providing the basis for presentation to the report of financial statements and ensuring the comparability between entities. The complete financial statements to be reported according to IASB (2021, p. A980–A981) are: “(a) a statement of financial position as at the end of the period; (b) a statement of profit or loss and other comprehensive income for the period; (c) a statement of changes in equity for the period; (d) a statement of cash flows for the period; (e) notes, comprising significant accounting policies and other explanatory information; (ea) comparative information in respect of the preceding period as specified in paragraphs 38 and 38A; and (f) a statement of financial position as at the beginning of the preceding period when an entity applies an accounting policy retrospectively or makes a retrospective

restatement of items in its financial statements, or when it reclassifies items in its financial statements”.

One area of the negative reporting is the GRI-Oriented Sustainability reporting as Hahn and Lulfs (2014) defend. The report must show the true and fair view of the organization and Global Reporting Initiative (GRI) provides standardized reporting guidelines allowing to disclose positive and negative indicators of an organization's sustainable performance. In this sense, the organization reports the annual evaluation of GRI indicators with total transparency and the assessment demands explanations for the negative results and solutions to the consequences.

One area of the positive reporting is the uncertainty as van der Bles et al. (2019) support in their framework of uncertainty communication. The report must identify the facts, numbers and explanation of the “*situation in which something is not known, or something that is not known or certain*” (Cambridge University Press 2021). Then, on the report, uncertainty demands that “*inherent part of knowledge, and yet in an era of contested expertise, many shy away from openly communicating their uncertainty about what they know, fearful of their audience's reaction*” (van der Bles et al. 2019, p. 2).

One of the newest areas of reporting is the accounting for climate that allows to describe climate-related matters and notes into financial reporting (CDSB 2020) which assess the increasing level of risks (political, legal, technologic, market, social, economic and financial) and opportunities (energy source, resources efficiency, products and services) that demand a strategic plan based on risk management with financial impact. As CDSB (2020, p. 12) argues “*range of forward-looking information is already embedded in financial reporting in areas such as fair value accounting, impairment testing, the measurement of provisions and the recognition of contingent liabilities*”.

One of the oldest areas of reporting is the aggressive financial reporting and the aggressive tax report in order to promote fraudulent reporting as Frank et al. (2009) research. We could observe, though, several scandals, such as: Enron

Corporation in 2001 or Parmalat SpA in 2003 using these type fraudulent strategies.

Although there is the general regulation about the financial statements, IAS and IFRS have been issued continuously to regulate the specific evaluation of assets, liabilities, equity, revenues and expenses. Furthermore, the annual report demands the report of the internal and external auditor to give more accuracy and reliability to the report, in general, and increase the quality of the accounting information to help stakeholders assess the annual reports and take the decision for the best allocation of their resources.

Summary

Reporting is the tool that an organization uses to communicate with their stakeholders, which allows to decrease the asymmetry of information and to increase the accountability. The first drive is the comparability of the report between organizations which is possible due to the international regulation, for example, IFRS Standards and IFRIC Interpretations provide framework to recognise assets, liabilities, equity, revenue and expenses. The second drive is the timeliness of the report between organizations which is mandatory to tax agencies, banks and shareholders and could be voluntary to other stakeholders with less authority.

Reporting Framework

Accountability

Definition

Since 2017, an increasing number of companies have started to disclose their nonfinancial information. This change has been driven both from a high degree of sensibilization to sustainable development and from the increasing number of forms of regulation about nonfinancial information. According to this evidence, the recent past has been characterized from the exigence to identify new reporting frameworks in order to disclose the different types of nonfinancial information. Specifically, the reporting frameworks are adopted by the companies that want to effectively disclose a standardized and comparable non-financial information towards their stakeholders.

The Differences Between Financial and Nonfinancial Reporting

In doctrine, there is no clear distinction between the concept of mandatory and voluntary disclosure (Quagli and Teodori 2005), and this lack implies the absence of a clear distinction between financial and nonfinancial information. The conceptual difference that exists between these categories of information often depends on the regulatory context in which a company operates. In this sense, what concerns the economic-financial sphere is required by law and what, instead, pertains to the qualitative sphere falls within the ambit of what is voluntarily accounted for.

With the term nonfinancial information, academics and practitioners refer, instead, to that set of information that concern:

- Sustainability considered as the set of actions and programs promoted by the company to guarantee a respectful and efficient productive activity in terms of environmental and social aspects.
- Governance, which includes elements properly related to aspects of form and substance that make up the governance of a company and how they relate to the corporate context, internal and external.
- Intangibles, or rather to that set of assets that make up the immaterial structure of a complex organization, expression, for example, of intellectual, relational, and social capital.
- Risks, in the broadest sense of that type of information that identifies the set of generic and specific risks of a company.

However, there is an obligation to specify that the incessant evolution of the global competitive context and the consequent emergence of new business models do not allow us to provide a precise definition of what is really meant by nonfinancial information. Specifically, increasing the amount of nonfinancial information beside the financial results allows the stakeholders to fulfill the gaps resulting from the disclosure of the single financial information.

However, regulators are pursuing a different approach limiting the amount of disclosure to prevent the disclosure of uncertain and deceptive information (Wyatt 2008).

The development of the reporting, over time, has led to an increase in the number of information communicated to the outside, thus favoring an anomalous process of widening the number of pages in the annual reports that, often, and especially in elephantine organizations, is equivalent to ineffective information. It goes without saying that it should be remembered, the expansion of information, from a stakeholder perspective, can be perceived as an asset, but only when this information is more useful for making investment decisions (Eccles and Krzus 2012); in reality what happens, especially in many organizations of considerable size, is that the annual report becomes a tool to carry out an exercise of information display, thus determining an unnecessary complexity in terms of readability. Also, literature has revealed how the disclosure of nonfinancial information can be used by managers with the controversial aim of providing a distorted image of the company through the use of impression management (Tata and Prasad 2015).

The approaches adopted by companies with respect to the theme of the link between financial and nonfinancial information can be different in practice depending on the different level of interdependence existing between the two types of information (Mio 2011).

In some cases, there is an absence of coordination without some form of correlation between them; such situation could risk generating at the communication level the presence of conflicting and nonaligned information. Frequent is the case in which, instead, the same information is present in different reports, where different are also the stakeholders to whom these documents are addressed. In these terms, companies have to interact with a heterogeneous panorama of interlocutors composed of stakeholders interested in the investment side of the company, communities sensible towards the social and environmental dimension of the disclosure, and governmental institutions that mainly focusing on the adherence on law requirements of the disclosed information.

It follows, for example, that in the presence of a risk arising from a compensation claim for environmental damage, the “stakeholder-investor” perspective, different from that of the “stakeholder-local community,” will determine, in the first case, the evidence of monetary aspects with respect to the analysis, in the second case, of the evaluation of externalities, often not measurable in monetary terms.

The Differences Between Different Types of Nonfinancial Reporting Framework

Within the theme of the connectivity of the information present in the Integrated Reporting, Paternostro (2013) refers to a scheme of representation of the interdependencies between financial and nonfinancial information and not, through the explanation of different types of reports. The following is a summary diagram showing the contents, the time horizon, the types of capital, the information, whether financial and/or non-financial, the information matrix (if qualitative and/or quantitative).

- Financial statement: Information on performance and company, past and present time horizon – financial capital – financial information – quantitative information.
- Management commentary: Information on several aspects, past, present, and future time horizon – financial and structural capital – financial and other information – quantitative and qualitative information.
- Social and environmental report (social and environmental report): Information on several aspects, past, present, and future time horizon – social and relational, human and natural capital – nonfinancial information – quantitative and qualitative information.
- Report on corporate governance (corporate governance report): Information on the company and governance, past and present time horizon – financial and human capital – financial and other information – quantitative and qualitative information.
- Reports on intellectual capital (intellectual capital report): Information on various aspects such as external environment, strategy, resource allocation and business model, past, present, and future time horizon – intellectual, relational, and human capital – especially other information – quantitative information and qualitative.

Some empirical cases have also highlighted the presence of cross-references, when in a document an explicit reference is made to another that presents more detailed information on a specific topic.

Less common, on the other hand, is undoubtedly the case of a coordinated disclosure that takes the form of drafting separate documents that are designed, prepared, and published in an autonomous but at the same time coordinated manner.

Lastly, the integrated disclosure represents a standalone topic due to the coordination between economic, environmental, and social aspects. Furthermore, it represents also a tool used by managers during decision-making processes. In fact, the integration of financial and nonfinancial dynamics under a common umbrella favors the development of forward-looking evaluations.

In this perspective, the IIRC has proposed a framework of disclosure with the aim of increasing the number of integrate reports around the world. Specifically, it aims to improve the quality of information provided to the financial capital providers, suggest a more efficient approach for companies for disclosing their material factors, and support the decision-making processes in the short, medium, and long terms. This framework constitutes a real paradigm shift where, in addition to the great support, it can give in terms of decision-making, the information tool presents strong elements of distinction with respect to traditional reports ranging from the communicative approach, to the impact on management, to the inter-functional logic, to the information focus, to the time frame of reference, to the principle-based approach, to the capacity for synthesis, to the openness to digital content.

On this last aspect, authoritative doctrine (Tapscott & Ticoll, 2003) considers, in this sense, that financial reporting alone is not able to guarantee high levels of transparency, understood as the possibility for institutional stakeholders to access information on issues relevant to their interests, if not supported by an integrated reporting process based on a web-based perspective. Specifically, the modern era communication is based on different platforms. For instance, the use of newspaper articles to disclose financial information is considered to be a single perspective channel of disclosure. On the other side, the Internet takes the transparency to a new level with a more dynamic and shared transparency.

It goes without saying that such a level of integration can guarantee a type of business communication:

- Two-way or relational due to the feedback received from stakeholders.
- Multiple in terms of information content, because it presents strategic-competitive, economic-financial, social, and environmental data.
- Diachronic, as regards time perspective, because it manifests references of a retrospective, concomitant, and prospective nature.
- Qualitative-narrative as well as quantitative-monetary, as to the nature and modality of the information provided.

The aforementioned is verified, moreover, in an international context in which the adoption of nonfinancial reporting tools concerning aspects such as intangible assets, KPIs (Key performance Indicators), ESG (Environmental, Social, and Governance), and the web-based approach.

These aspects are fully accepted in the Integrated Report, a tool with respect to which the ferment is not only great about the different perspectives of analysis (Dumay et al. 2016) at a scientific level, but also with respect to the numerous managerial implications. Specifically, integrating financial, management, governance, and sustainability information in a single document coherently explains the company's strategy and the future perspectives and provides an optimal

picture of the company activity and management to the stakeholders.

Summary

The increasing attention paid by internal and external stakeholders on firms' activity has favored the rapid growth of new form of reporting standards. Specifically, this phenomenon has regarded both the traditional annual reports prepared in according to the laws and the standalone reports prepared on voluntary basis. Furthermore, during the last years, an increasing number of business organizations have started to disclose their nonfinancial information through integrated reports. However, the exigence to disclose the largest number of information in order to engage with stakeholders required the identification of new reporting frameworks. Specifically, this exigence regards the new form of corporate reporting through websites and social media. In this sense, the academia could interact with practitioners in order to identify new form of reporting in order to increase the overall degree of nonfinancial information transparency.

Country-by-country reports of payments to governments

Definition

Reports of payments to governments are a form of public country-by-country (CbC) reports. Reports of payments to governments are reports through which multinational companies disclose, to the public in general, more or less detailed information on where they have undertaken their activities and generated their revenues and profits, as well as other relevant information such as information about taxes paid and subsidies received.

Introduction

The notion of transparency has become one of the most important when discussing proposals for new types of public reporting by corporations. This importance is undoubtedly associated with the idea that corporate transparency is useful in fighting tax avoidance and corruption. These phenomena, tax avoidance and corruption, are certainly among the corporate practices most damaging to the corporations' reputation and the public's trust in them. The 2017 Edelman Trust Barometer (Edelman 2017) reports that when asked "What can businesses do that would cause the most damage to your trust in a better future?", amidst the top five most-selected responses, one can find the following two: "pay bribes to government officials to win contracts" and "move profits to other countries to avoid taxes."

On the importance of transparency and public reporting, Choudhury (2016, p. 185), resorting to a very recent example, asserts their importance from a social regulation point of view by emphasizing that "when the UK government determined that there was an insufficient number of women on corporate boards," rather than requiring corporations to "increase the number of women in management," it mandated instead "that they disclose the number of women holding managerial positions within firms." Another example comes from India, where the government also "focused on disclosure" when it "became concerned about the country's energy usage" and required "corporations to report on corporate efforts to conserve energy" (*ibid.*). One final example comes from the USA, where, "in an effort to curtail the violence in the Democratic Republic of Congo (DRC), Congress directed the Securities and Exchange Commission to mandate corporate disclosure when using conflict minerals" (*ibid.*).

Among the new types of reporting designed to help companies to be more transparent is the reporting of payments to governments. Reports of payments to governments are a form of CbC reports (Murphy 2016; Wójcik 2015) that detail the monetary streams pertaining to a multinational corporation's relations with the governments of the countries in which they operate. This type

of reporting has arisen and developed as a result of the civil society organizations' concerns related with phenomena such as corruption and tax avoidance, as well as multinational corporations' increasing power and environmental responsibility (Wójcik 2015). Murphy (2016, p. 97) goes as far as considering that "the contention that globalization is not working for the benefit of everyone" lays in the origin of the demand for CbC reporting. According to this expert in CbC reporting, "some nation states and large parts of the world's population have lost out as the power of the global corporation has risen, including its power to not pay tax in the right place at the right rate and at the right time" (p. 97). The issue of taxation is nowadays inextricably linked to the issue of inequality. A testimony of this is the recent intervention of the Dutch historian Rutger Bregman at the World Economic Forum (WEF) in Davos. In a panel on inequality developed in partnership with the Time magazine, Rutger Bregman asserted that the main issue at hand when discussing inequality was "taxes, taxes, taxes, and all the rest is bullshit in my opinion" (Elliot 2019).

The focus of this entry is on public CbC reporting, in the form of the reports on payments to governments, rather than on CbC reporting to tax authorities. CbC reporting to tax authorities is also an important way of addressing the concerns mentioned above. This reporting for multinational companies is now well-known because of the OECD action plan on base erosion and profit shifting (BEPS), according to which information on these matters is to be provided to tax authorities (Murphy 2016). However, the focus of this entry is on the requirement to make publicly available the income generated, taxes paid, and other related information on a country-by-country basis.

Reporting on payments to governments is closely linked with corporate social responsibility (CSR) and sustainability reporting. In a 2013 document, KPMG considered that "while diversity and sustainability have been the vanguard of CSR, anti-corruption and tax arguably constitute the next wave" (KPMG 2013, p. 2). Whereas the issue of the fight against corruption is nowadays a

well-established aspect of CSR and sustainability reporting, the same is not the case of tax evasion. The most important CSR-related instruments include corruption as an important aspect of CSR. The OECD Guidelines for Multinational Enterprises, the United Nations Global Compact, and the Global Reporting Initiative (GRI) all attribute great importance to corruption. For example, the GRI Standards include a specific standard devoted to corruption (GRI 205: Anti-corruption). Regarding the case of taxation, whereas the OECD Guidelines for Multinational Enterprises includes a full chapter on taxation, the standard ISO 26000, providing guidance on social sustainability, has only one brief mention to taxation. The GRI Standards do not include a specific standard on this matter at all. However, the standard "GRI 201: Economic Performance" requires companies to provide information on the "Direct economic value generated and distributed," including "payments to government by country."

Key Issues

Reporting on payments to governments has developed enormously in the past few years, at least when considering the legislation pertaining to this type of reporting. It has become mandatory in such important regions and countries as the European Union (EU) and Canada. In the EU, large companies in the extractive industries (oil, gas, mining, and forestry) are obliged to provide information on the taxes that they pay and on some additional aspects of their relations with governments for each country in which they operate. This was through the so-called New Accounting Directive, which was approved by the European Parliament in June 2013 (European Commission 2013).

According to the New Accounting Directive, paragraph 44, "to provide for enhanced transparency of payments made to governments, large undertakings and public-interest entities which are active in the extractive industry or logging of primary forests should disclose material payments made to governments in the countries in which they operate in a separate report, on an annual

basis.” This report “should incorporate disclosures on a country and project basis” (par. 45). The information that such large undertakings are required to disclose is the following (article 43):

- (a) the total amount of payments made to each government;
- (b) the total amount per type of payment;
- (c) where those payments have been attributed to a specific project, the total amount per type of payment made for each such project and the total amount of payments for each such project.

Besides the large undertakings from extractive industry or logging of primary forests, the EU, also in June 2013, also made mandatory the disclosure of payments to governments by banks and investment firms. Directive 2013/36/EU, “on access to the activity of credit institutions and the prudential supervision of credit institutions and investment firms,” mandated that:

“From 1 January 2015 Member States shall require each institution to disclose annually, specifying, by Member State and by third country in which it has an establishment, the following information on a consolidated basis for the financial year:

- (d) name(s), nature of activities and geographical location;
- (e) turnover;
- (f) number of employees on a full time equivalent basis;
- (g) profit or loss before tax;
- (h) tax on profit or loss;
- (i) public subsidies received.”

In Canada, there is legislation similar to the one proposed in the New Accounting Directive, the Extractive Sector Transparency Measures Act (ESTMA), which dates from 2015.

With regard to the legislation on reports of payments to governments in the EU, two relevant reports examining how it has been applied have already been published. The first examined the implementation of mandatory reporting of payments to governments by the extractive sector in the UK (Chatzivgeri et al. 2017). The second report

extended this work to examine the wider EU context (The STAR Collective 2018). Albeit acknowledging that “there is scope for improvement” in terms of a number of issues (p. 5), the authors of this latter report declare having “found substantively positive findings in terms of the usage of the reports and how the EU’s reporting requirements in practice were perceived by the corporate world” (p. 4). They also mention examples of good reports on payments to governments. For example, in terms of “disclosure of additional tax information,” the reports of payments to governments prepared by Rio Tinto and BHP Billiton were considered as giving “users a much fuller picture of companies’ commitment to good tax citizenship” (p. 36). These reports “provide numerous examples of additional disclosures which provide users with a better understanding of the companies’ attitude towards paying taxes” (p. 33).

Future Directions

One of the most important recent initiatives that is likely to lead to further developments in reporting on payments to governments is the “proposal for a Directive of the European Parliament and of the Council amending Directive 2013/34/EU with regard to disclosure of income tax information by certain undertakings and branches” (European Commission 2016). According to this proposal, MNE groups with a total consolidated group revenue of over EUR 750 million will be required to “draw up and publish a report on income tax information on an annual basis” (art. 48b). The information to be required from these corporations, on a country-by-country basis, is the following (art. 48c):

- (a) a brief description of the nature of the activities;
- (b) the number of employees;
- (c) the amount of the net turnover, which includes the turnover made with related parties;
- (d) the amount of profit or loss before income tax;
- (e) the amount of income tax accrued (current year) which is the current tax expense recognised on taxable profits or losses of the financial year by undertakings and branches resident for tax purposes in the relevant tax jurisdiction;

- (f) the amount of income tax paid which is the amount of income tax paid during the relevant financial year by undertakings and branches resident for tax purposes in the relevant tax jurisdiction; and
- (g) the amount of accumulated earnings.

Another important initiative related to the development of this type of reporting is GRI's Global Sustainability Standards Board (GSSB) 2017 Project Proposal related to "Disclosures on tax and payments to government." A multi-stakeholder committee of experts was appointed by the GSSB to develop a draft Standard on this matter, and an exposure draft was developed and submitted to public comment. The GSSB received a number of public comments which will be considered by the committee in the development of this new GRI standard. According to the most recent information provided by the GRI (2019), this new standard will be considered as an economic standard and will be known as *GRI 207: Tax*. "The Standard's development process is currently under review by the Due Process Oversight Committee. Subject to final approvals, it is anticipated that the Standard will be made available for public use in December 2019" (GRI 2019).

Residual Claimant Theory

Min Yan

School of Business and Management, Queen Mary University of London, London, UK

Synonyms

Residual owner

Background

With the development of law and economics discipline, agency theory becomes the force of theoretical understanding of corporate governance. In particular, Armen Alchian and Harold Demsetz's seminal paper *Production, Information Cost, and Economic Organization* and Michael Jensen and William Meckling's *Theory of the Firm: Managerial Behaviour, Agency Cost and Ownership Structure* in 1970s offered a contractual understanding of company opposed to the traditional standpoint. The company in the eyes of Alchian and Demsetz (1972) does not own any of its inputs; rather it is the owner of various resources both tangibly and intangibly through the "cooperative specialization" to increase productivity, and as a result the company is viewed no different from "ordinary market contracting between any two people" (p. 777). For example, a relationship between an employer and an employee within a company is seen the same as the relationship between a customer and a grocer. A customer can fire her grocer by stopping buying from him, can assign her grocer task of obtaining any item to sell at a mutually agreeable price, and can even punish her grocer by filing a lawsuit if defective goods are provided by the grocer, and these are all an employer can do to her employee (Alchian and

Demsetz 1972). Put differently, company is deemed as an artifact of continuous re-negotiating contracts or a "legal fiction which serve as a nexus for a set of contracting relationships among individuals" (Jensen and Meckling 1976, p. 310). Or in Fama's words, "The firm is just the set of contacts covering the way inputs are joined to create outputs and the way receipts from outputs are shared among inputs" (Fama 1980, p. 290). Ownership of company gets to be irrelevant from this contractarian aspect.

Shareholders are therefore regarded as the input owners of equity capital, same as the input owners of labor, credits, raw materials, or others. Input owners cooperate within the company to strive for enhanced productivity with their respective comparative advantages and thereby for higher rewards. However, there is a problem to ascertain the rewards when all those input owners are working as a team. The final output is usually not separable which means each individual's contribution to the output is difficult to identify. Just as pointed out by Alchian and Demsetz (1972), when the productivity and rewards are highly and accurately related, then the input productivity would be greater; otherwise input productivity would become smaller if there is only a loosely correlated relationship. Put it simply, given that one can shirk without being punished, the incentive to shirk will be large since only a small percentage of losses caused by the shirker would be borne by herself and the large part would be borne by others. So, it is of great importance to reward each input owner as team member correctly in order to incentivize higher productivity.

One viable option is through observing the behavior of individual input owner to ascertain their contribution. But the monitoring is costly, and we cannot completely rely on the market due to the information asymmetry and no less incentive to shirk for new substituents. Alchian and Demsetz (1972) thereupon suggested to entitle the ultimate monitor the *net earnings of the team, net of payments of other inputs* (p. 782). That is, let the ultimate monitor to be the residual proprietary claimant to earn "his residual through the reduction in shirking that he brings about, not only by the prices that he agrees to pay the owners

of the inputs, but also by observing and directing the actions or uses of these inputs,” and with the enhanced incentive, the monitor with residual proprietary claims would no longer shirk as in the past (Alchian and Demsetz 1972, pp. 782–783). Shareholders are chosen to be such monitors and thereby entitling them all the residual claims.

Definition and Implications

The residual claimant theory holds that after fixed claimants have received their compensation for their contribution, the residual claimant could catch whatever is left from the income stream. In the corporate context, shareholders are treated as residual proprietary claimants who could “reap the marginal dollar” of the corporate profits and “suffer the marginal dollar” of any corporate losses as well (LoPucki 2004, pp. 1343–1344). They are entitled, and only entitled, what is left from the income stream after all fixed claims are met. As the recipients of the residual cash flow and income stream, in a healthy and solvent company, shareholders would therefore have the greatest impetus to maximize the wealth of the company since they could seize the entire, or at least most of, surplus after the fixed claims of other stakeholders are satisfied (Macey 1999; Bainbridge 2008).

Such gain allocation rule allows shareholders to catch whatever is left from the income stream and thereby tightly ties their benefits to the performance of the company. The residual claimants’ wealth could be maximized in the event that company wealth is maximized on the ground of that residual nature. As residual owner, shareholders could obtain higher dividends and share value when the company runs well while get less or even lose all their investment if the company runs badly. In particular, the position in the allocation sequence of corporate profits underlines shareholders’ eagerness to pursue the success of the company. Contrary to the so-called definable and compulsory returns, such residual risk-bearing nature could stimulate those residual claimants choosing, and wholeheartedly supporting, the best investment project for the

development of the company. It follows that maximizing the wealth of shareholders could be equated with maximization of the company wealth owing to the residual nature that, in turn, would foster the economic efficiency and benefit the society as a whole. Just as some scholars commented, the aggregation of all shareholder interests in a company is equivalent to the company’s interests (Yap 2010).

Problems

There are however several problems existed in the residual claimant theory. To begin with, shareholders are normally not entitled to claim dividends or any profits in a solvent company. It is in fact the board of directors who has the control of its deposition and decides where the residual should go. Directors in most jurisdictions have the right to decide not to pay shareholders dividends and instead deliver the residual to non-shareholding stakeholders by retaining the profits for future business, increasing employee benefits, improving customer service, and expanding the R&D, among others. Shareholders cannot get anything, at least directly (Stout 2012), unless the board decides to pay them. Due to the independent personality of company, shareholders cannot enjoy corporate profits directly in most jurisdictions unless directors so decide, and they are not allowed to direct companies including forcing board to declare dividends. Rules empowering the board of directors the right to determine how to utilize and allocate the assets in all the major jurisdictions significantly compromise the argument that shareholders are the residual claimants who are entitled to “every penny of profit left over after the firm’s contractual obligations to creditors, suppliers, and employees have been met” (Blair and Stout 2006, p. 728).

Only in insolvency law, shareholders may get the residual after the claims of employees, creditors, and others being fully satisfied. Nevertheless, even under such context, shareholders are by no means the only and appropriate residual owners under all the circumstances. Just like the simple and straightforward example illustrated by

Professor Lynn LoPucki (2004), in a company which is at the vicinity of insolvency, if the unsecured debts owed by the company are much more than its assets, it would be the unsecured creditors who own the residual, namely, the remaining assets after the outstanding taxes, employees, or secured creditors are fully paid off. "All of the gains and losses from action" taken during the reorganization, for example, would therefore fall to the unsecured creditors instead of shareholders under this circumstance. In addition, stakeholders such as employees who make the firm-specific investment could also be seen as the residual proprietary claimants since under such situation they would also lose out. According to Lynn LoPucki's (2004) empirical study, the identity of the residual owner is difficult to ascertain, and indeed, multiple residual owners exist with differing priority levels.

Another important justification for the residual claimant theory is the issue of incentive. As shown above, shareholders are argued to have the greatest incentive to maximize the company wealth and monitor directors' accountability due to the so-called residual position. On the other hand, non-shareholding stakeholders, it is argued, have no incentives to advance the corporate success (Sundaram and Inkpen 2004). Their interests are regarded to be hardly, if not impossible, aligned with corporate performance. In other words, if stakeholders only have fixed claims, such as monthly interest and salaries among other fixed payouts, then creating any marginal profits cannot make any difference to them as fixed claimants, and they thereby have little impetus to maximize the company value. It is argued that stakeholders as fixed claimants "do no better whether the firm performs *spectacularly well* or *just well*" (Sundaram and Inkpen 2004, p. 354).

Nevertheless, stakeholders can also catch benefits more than their fixed claim. Take local community/government, for example; if a company runs well, it can definitely collect more tax revenues. This means the local administration would also have incentive to improve the infrastructure and provide more convenient facilities among others to attract the company stay in its area and help corporate growth because they can catch

more in addition to the so-called fix claims. Similarly, employees may also have the right incentive to help the company perform better as it is not uncommon for employees in a well-performed company to get generous bonuses in addition to wages, and the better performance the company has, the more bonus the employees can obtain. Creditors and suppliers would also get more security for their contribution when companies run well. Thus, stakeholders are in effect able to obtain a fraction of extra benefits, namely, the residue, apart from the so-called fixed rights to a particular flow of income stream, and such incentive can be made explicit in advance like the design of performance-based salary and bonus. Put differently, stakeholders' claims are not entirely fixed. Take employee, for example; although their wages are normally fixed claims, other rewards such as bonus and certain retirement benefits are definitely unfixed. So, stakeholders can also have the incentive to impel directors to run companies better.

With regard to the argument of residual risks, which is related to that of incentive, shareholders are not the only group who undertake them. A creditor may lose her interests as well as principal when a company fails. A supplier provides highly specialized products and services to a given company which may be devaluated or completely worthless to other companies; if the company runs badly or fails, the supplier would lose out in view of the fact that the specialized production line and machinery might be useless. Similarly, an employee who wishes to join a certain company may invest a large amount of time, energy, and money to develop specialized and unique set of skills required by the company. Such employee's fate would be then closely linked with the company on grounds that her specialized firm-specific skill may be useless for other companies. Stakeholders therefore assume the risks as well. Moreover, the limited liability of shareholders means part of the residual risk has already been shifted to other stakeholders such as creditors. On the ground that the liability of shareholders would not exceed the initial investment, around some critical point like in the vicinity of corporate insolvency shareholders may take excessive risks to

‘gamble’. Under these circumstances, shareholders have no material interests, namely, they have few chances to be paid, and they as economic actors have no reason to resist very risky investing projects. There is severe potential of externalization because shareholders are able to “reap of all the benefits of risky activity but do not bear all of the cost” (Easterbrook and Fischel 1991, pp. 49–50). For the worse, in the event that shareholders have possibly no chance to get anything, shareholders would have a more vociferous preference to precede high-risk activities, especially when these shareholders lose the incentive to increase any margin since their residual claim has gone under water in this setting. Just like Professor Gregory Scott Crespi (2007) has pointed out, there is a vicinity of insolvency inefficient investment incentives problem. Of course, even in an ordinary situation, such a phenomenon of disproportionate gain by externalizing costs remains. On the one hand, their losses would never exceed what they have already paid; and on the other hand, the costs are borne partly by creditors among other stakeholders (Easterbrook and Fischel 1985).

Summary

As a result, the standpoint that shareholders have most to lose or to gain in the context of residual claimant theory is not always accurate. Especially when considering the fact that shareholders nowadays usually diversify their investment and thereby the risk by adopting a diversified portfolio strategy, their interests are not always identical to the company’s best interests as previously discussed. The incentive argument for shareholder is not tenable. The risk-preferred strategy for shareholders when they are able to diversify unsystematic risks or close to insolvency with little hope to be paid might be correspondingly different from the interest of the company and other stakeholders. While shareholders can diversify their unsystematic risk, company cannot. If directors are required to act for shareholder interest, then they may only focus on the systemic risk and leave the company vulnerable to idiosyncratic risk (Yan 2015).

We can see unsecured creditors own the residual of what secured creditors left while shareholders could still be called ultimate residual claimants by definition. In other words, shareholders could be always deemed as the last persons who have a claim on whatever is left after all other claimants’ claims are met, even if they have little chance to seize any surplus due to their sequence being in the very end and the cash flow having little possibility to move to them. However, thanks to the limited liability rule, under such situation shareholders have much to gain and little to lose from taking excessive risks, the conventional incentive argument becomes untenable, and residual claimant theory therefore cannot support the shareholder-centered model anymore. In particular, with the development of financial derivative, shareholders are not necessarily affected by company’s decision under certain conditions. Indeed, they can be indifferent to corporate performance and alienate their personal interests from their shares. Take hedge funds, for example; they may not care about the decline of share price as it is possible for them to profit from the bad performance. Especially when they sell short the shares, declining of share price rather than increasing is desired.

Adaptability; Elasticity; Equilibrium; Flexibility

Definition

Resilience is the ability, competence, or capability to endure and overcome a change caused by a disturbance, shock, or stress.

Background

The word *resilience* has its origin in the Latin word “*resi-lire*,” which means *springing back*. The concept of resilience has become a ubiquitous concept (Meerow and Stults 2016) rooted in different worldviews and scientific traditions such as psychology, ecology, and engineering (Teigão dos Santos and Partidário 2011). The concept of resilience evolved from psychology in the 1940s (Manyena 2006). Resilience entered the field of ecology when systems thinking became popular. Crawford Stanley Holling (1973) defined a concept of ecological resilience in order to “understand the capacity of ecosystems with alternative attractors to persist in the original state subject to perturbations” (Holling 1973). In engineering, the concept of resilience was first used to “explain elasticity and describe a material’s ability to withstand an external shock” (Davoudi 2012). Multiple meanings of the concept have since emerged; it is used in various fields and settings.

Specified resilience is concerned with problems related to aspects of a system that might arise from a set of sources. *General resilience* means resilience to all kinds of disturbances, shocks, or stresses faced by ICT-networks, communities, societies, economies, ecosystems, or socio-ecological systems (e.g., Folke et al. 2010; Hollnagel et al. 2010). In this entry we: (a) identify the core of the concept of resilience, and (b) analyze how resilience is used in different contexts (individual, social, and planetary contexts).

What Is the Core of Resilience?

In general, resilience is related to “a system’s ability to endure and overcome a change” (e.g., Fox-Lent et al. 2015; Madni and Jackson 2009). It

is “the ability to prepare and plan for, absorb, recover from, and more successfully adapt to adverse events” (NRC 2012). In human sciences, resilience refers to a competence or a trait by which people return to equilibrium after a shock or a stress in an individual, organizational, societal, or socio-ecological context. Resilient people have the ability to “cope with external stresses and disturbances as a result of social, political, and environmental change” (Adger 2000, p. 347).

Resilience is a bridging concept between disciplines and approaches stimulating interdisciplinary understanding (Davoudi 2012). It provides a framework for understanding interdependencies between ecological and social fields (Welsh 2014) and it offers a solution to the paradox of *stability* and *change* that are both needed in order to have transformation in *individual* or *collective* life (e.g., Ahern 2011). The dynamics of resilience are demonstrated in Picture 1. The core of resilience has something to do with maintaining equilibrium. On the other hand, elasticity is needed because development and progress refer to changes and transformations. For example, adaptability and transformability is a basis for social-ecological system resilience: adaptive capacity maintains certain processes and transformability means the capacity to create a fundamentally new system when needed (Folke et al. 2010).

Resilience can be understood as a perspective, rather than as a neatly defined notion (Brand and Jax 2007). The meaning of resilience may also be

culturally or contextually dependent (Eggebert 2018). This is essential in order to have equitable resilience in a specific context. Equitable resilience simultaneously deals with social vulnerability and differential access to power, knowledge, and resources. The starting point for equitable resilience is people’s subjective perception of the position they have. This “accounts for their realities and for their need for a change of circumstance to avoid imbalances of power into the future” (Matin et al. 2018).

In its largest sense, resilience is a descriptor of complex system dynamics. It helps to understand interconnections between inequality, climate change, and biodiversity. The roadmap from such problems toward a sustainable future depends on new social structures, but also behavioral changes of citizens are needed (United Nations 2015). This deep and large regenerative process underlines a new narrative created from notions of resilience and sustainability (Gillard et al. 2016). The new narrative is related to the capacity for continuous reconstruction. Both individuals and communities are key actors in deliberating transformation toward the shared local understanding (Hamel and Välikangas 2003; Ziervogel 2016).

Resilient systems, organizations, and societies are diverse. They are characterized by robustness, resourcefulness, and rapidity to recover (Ganin et al. 2016; Larkin et al. 2015; Ayyub 2014; Francis and Bekera 2013; Bhamra et al. 2011). Resilient people accept reality and they have the ability to improvise (Coutu 2002). From the point of view of systems thinking, there is evidence that the stability of any system is based on diversity. Systemic risks can be minimized by enhancing the diversity of the operational environment (Haldane and May 2011).

Resilience, Picture 1 Dynamics of resilience

How Resilience Is Used in Different Contexts?

Resilience is used in various fields, settings, and scientific traditions. We identified five partly overlapping contexts for resilience in recent academic research: (1) Psychological resilience,

(2) Sociocultural resilience, (3) Urban resilience, (4) Resilience in economics, and (5) Socioecological resilience.

Psychological resilience has positive correlations to quality of life. Resilience, taken from the clinical psychology point of view, can be described as a personal ability to cope with a stressful situation and to maintain internal balance and continue successful activity (Diržytė et al. 2017). Researches into psychological resilience deal with, for example, obligations felt (Greenfield 2009), well-being at work (Liu et al. 2018; Slater et al. 2018), aging (Landes et al. 2014), social support (Hill et al. 2014), and vulnerability (Cipolla 2018). Thus, resilience has an essential role to play in individuals' subjective well-being (Yildirim and Belen 2019).

Sociocultural resilience deals with cultural traditions (Daskon 2010), cultural heritage (Gandini et al. 2017), religion (Annalakshmi and Abeer 2011), trust (Pierce et al. 2014), ethics (Barrett et al. 2016), and education as a tool for adding understanding of resilience in a society (e.g., Gamman and Thorpe 2018).

Local culture and traditional values and how to support and recognize them are critical for resilience. People's skills, customs, values, common experiences, moral, and spiritual systems are important for resilience in livelihood (Daskon 2010). Identified and perceived system boundaries, purposes, and timescales frame individual stakeholders' perspectives and perceptions of resilience. This also refers to innovations.

Sociocultural resilience building is substantially about innovation and experimentation (Schauppenlehner-Kloyber and Penker 2016). Therefore, a connection between education and resilience is evident. Abstract reasoning and anticipation skills obtained through education help to "undertake preventive measures without needing to first experience the harmful event and then learn later" (Hoffmann and Mutarak 2017).

Innovation in general can be a matter for democracy because grassroots innovation can contribute to social justice and environmental resilience (Smith and Stirling 2016). Anne Eggebert (2018) stresses the value of networks

and relationships in a society: shared processes, for example, during studies in school can help to build individual, collective, and cultural resilience (Eggebert 2018). Human resilience is both a result of learning and a trait (Laird et al. 2019).

Urban resilience has become the key concept to understand existing urban dynamics. It is also a concept to use in responding to the challenges that are emerging while creating livable urban futures (Romero-Lankao et al. 2016) because "release and reorganization are essential to the full cycle of adaptive renewal, thereby conferring survival, resilience, and future" (Burton 2010). In urban areas, resilience is intertwined with sustainability and disaster management such as the perennial issues of vulnerabilities, risks, and adaptability (Kim and Lim 2016). Equitable urban resilience supports development that is contextually rooted, responsive to change, and socially just (Matin et al. 2018). Due to this, in urban planning, resilience and sustainability are often used as synonyms (Suárez et al. 2016).

Development, progress, and innovations always happen between exploitation and conservation. Due to this, flexible urban governance is needed in order to create urban resilience (Boyd and Osbahr 2010). Urban resilience is related to interactions between social and technical systems (Taysom and Crilly 2017). Resilience of both human and technology is remarkably similar. It is related to the "ability to sense, recognize, adapt and absorb variations, changes, disturbances, disruptions and surprises" (Hollnagel et al. 2006). Urban resilience also covers, for example, the important role of quality of life (Diržytė et al. 2017).

Resilience in economics is related to "the ability of the system to withstand either market or environmental shocks without losing the capacity to allocate resources efficiently" (Perrings 2006, p. 418). Resilience in economics deals with themes such as recovering from a recession (Ormerod 2010), the effects of climate change in economics (Simane and Zaitchik 2014), unusual conditions (Wamsler and Brink 2014), supply chains (Mari et al. 2014), and nonprofit firms (Larsson et al. 2016).

Socio-ecological resilience is closely related to the resilience of economics. It is “capacity of a system to absorb a disturbance and reorganize while undergoing change” in the face of a fluctuating environment (Walker et al. 2004). Therefore, socio-ecological resilience refers to climate change (Kim and Lim 2016; Ziervogel et al. 2016), land-use (Mansergh 2010), and forest alteration (McWethy et al. 2010).

Resilience thinking calls for capacity-building processes as exceeding thresholds “might precipitate a forced transformation to some state outside its Holocene stability domain toward an Anthropocene Era, society must seriously consider ways to foster more flexible systems that contribute to Earth System resilience and to explore options for the deliberate transformation of systems that threaten Earth System resilience” (Folke et al. 2010). Capacity-building can guide individuals, organizations, and governments in generating reflexivity about how to respond better to complex problems (Boyd and Osbahr 2010). The baseline of the strengthened transformative capacity is formed by agency and a sense of social cohesion (Ziervogel et al. 2016). Resilience is a constantly evolving evolutionary process (Kim and Lim 2016).

Summary

Since first used in psychology and ecology, multiple meanings have emerged for the concept of resilience. Resilience is a bridging concept between individual, social, and planetary approaches. In its largest sense, resilience is a descriptor of complex system dynamics. Resilience is related to a system’s ability to endure and overcome a change. It is a dynamic concept: the core of resilience has something to do with maintaining equilibrium, on the other hand, elasticity is needed because development and progress refer to changes and transformations. Therefore, resilience can also be understood as a perspective, and the meaning of resilience is culturally or contextually dependent.

Synonyms

Territorial resilience community; The resilient sustainability

Definition

Conceptualizing resilience and sustainability allows us to perceive the existing differences and complementarity in terms of a process of action that seeks to create defense mechanisms and progression, in face of adverse contexts or change, requiring new skills and joint strategies of action. Interpretation implies a systemic approach, resulting from acting forces in contexts of fragility and uncertainty, promoting initiatives of rebalancing and progression, toward sustainability and development. Resilient sustainability has a territorial application and implies collective dynamics, which on the whole presuppose to attenuate or overcome adversity, allowing the maintenance of conditions for the continuity of social organization, natural resources, and cultural values. In this context, the actions of the communities and the policies developed are fundamental to generating synergies that propel optimism and constructive attitudes toward territorial sustainability. Sustainable communities, and therefore resilient in the forms and processes of social and economic action, are structurally organized and cooperative, promoting actions to safeguard and protect their status quo while revealing the capacity and flexibility to restore the structure and vitality of their community.

Introduction

Resilient sustainability is a dynamic process of transformation to a more desirable trajectory, accepting continuous (permanent deformations and changes) of the systems and going beyond the concepts of limit and threshold (Davoudi et al. 2013). Thus, resilience must be perceived as the capacity of a social system to preserve its organizational configurations and functions, reorganizing itself and promoting concerted actions of reestablishment and self-control in the face of contextual change or threats, creating collective work contexts, cooperative and articulated for the perceived changes and identified challenges. It presupposes creative actions and concerted strategies capable of mobilizing communities and stakeholders for collective goals and development promoters. Initiatives should have a dimension of involvement of local actors (governates, investors, and the population) in an approach to preserving and enhancing natural and cultural resources.

Background and Meaning

Resilience, initially developed by Holling (1973) as a concept associated with an ecological research context, has been applied in recent decades to the social and economic fields, seeking to infer behaviors and evaluate the feedback produced (Tóth 2015). This concept emerges in the regional studies, given the interest in evaluating the dynamics between the territory and its actors in the construction of balances. The term reflects its Latin root “resiliere” has inherent Latin origins, meaning “to leap or bounce back, to pull back, to retreat, to shrink (go back).” Nowadays the term resilience has become a highly attractive and used buzzword in approaches to socio-economic contexts and in particular those that reveal resistance and overcoming in the face of contexts of loss or crisis (Bristow and Healy 2014; Fingleton et al. 2012). There is a widespread use of the term/concept without yet an agreed and unambiguous

operational conceptual principle, resilience, as usually employed or used, has multiple meanings and different contexts (social, economic, climatic, biological, etc.). Walker et al. (2004: 2) present resilience as “the capacity of a system to absorb disturbance and reorganize while undergoing change so as to still retain the same function, structure, identity and feedbacks.” In practice resilience as a “descriptive concept gives insight into the dynamic properties of an ecological-economic system. Sustainability as a normative concept captures basic ideas of intergenerational justice when human well-being depends on natural capital and services” (Derissen et al. 2011: 67). The dynamic established in the territorial relationship between the communities and their social and productive activities, geography, and natural resources determines a joint process that, in the context of change and/or imbalance, allows to promote sustainability and development. “The sustainability of development depends on its ability to prevent new risk creation and the reduction of existing risk” (Hudson 2009: 12). When we look at the concept of sustainable development and its interpretation, we see that, in structural terms, it is sustained by economic, environmental, and social well-being. The interaction and reconciliation of these three components is fundamental to the pursuit of sustainable development and the consequent achievement of well-being (Fig. 1).

Territories that present major structural weaknesses, as a result of their geographical specificity or their economic and social development, seek to develop mechanisms of action that allow creating conditions for the maintenance of their communities, economic activities that sustain and promote process of conservation and enhancement of natural resources (Strickland-Munro et al. 2010; Simmie 2014). These processes, leveraged in creative strategies and in the promotion of differentiated collective initiatives, contribute, of diverse nature, to socio-economic and environmental sustainability. It should be noted that this resilience is the result of synergies developed by their communities and the interaction with adjacent areas,

Resilient Sustainability, Fig. 1 Structural factors of the resilient sustainability process and its implications in socio-economic and territorial organization

built, formally and informally, processes of resistance to contexts of change (less social and economic dynamism) or geographical conditions of specificity, which require higher costs (accessibility, access to resources, investment, etc.). Essentially, and according to Béné et al. (2012: 48), building resilience would require “interventions that strengthen the three components: absorptive resilience, adaptive resilience, transformative resilience, together, and at multiple levels (individual, family, community, regional, etc.)” promoting flexible processes of qualification for change and reorganization. “Resilience itself confers a measure of the capacity of a system to absorb disturbance and reorganise, while undergoing change, with the same or similar system retained” (Folke 2006: 258). Hartman (2018: 69) relates a “set of six key conditions towards building destination resilience: 1) variety and redundancy; 2) connectivity; 3) polycentric governance; 4) environmental sensitivity; 5) learning and reflexivity; and 6) adaptive thinking and systems.” In this context, “community

resilience as the ability to anticipate risks, limit impacts, and rise again quickly through survival, adaptation, evolution, and growth in the face of changes” (Community and Regional Resilience Institute 2013). “The permanent capacity of a territory to devise and deploy new resources and capacities that allow them to anticipate, prepare, respond and adapt favorably to the dynamics of transformation driven by this changing environment is called territorial resilience” (Sánchez-Zamora et al. 2016: 109). “Resilient communities have a variety of employment opportunities, various income, as well as a variety of financial services facilities from financial and social institutions; and they are able to manage their natural assets and resources in addition to having the ability to protect, enhance, maintain and mobilize natural and community resources” (Community and Regional Resilience Institute 2013). Resilient and sustainable communities are defined as structurally organized and interacting to minimize the effects of change while having the ability to recover by restoring the vitality and socio-

economic dynamics of the community (Tobin 1999). “Resilience affords a system the capability to adapt, enabling a buffer effect by which the system can better absorb or withstand disturbances” (Walker et al. 2004: 28). Processes that include the preservation of their structures and the restoration of the essential basic functions that represent and shape the system or community under analysis (UNISDR 2009; Adger 2000). In this context, the concept of resilience gains relevance and application, integrating increasingly the discourse of politicians, economic and social organizations, businessmen, and citizens. Its meaning and scope create bridges and communication platforms between scientific areas, administrative entities, economic and social players, and the community itself, generating approaches and communication/dialogue processes among which there was no history of reflection and collaboration (Béné et al. 2012).

Resilient sustainability is a dynamic process of transformation to a more desirable trajectory, accepting continuous (permanent deformations and changes) of the systems and going beyond the concepts of limit and threshold (Davoudi et al. 2013). In this framework, resilience should be considered as a capacity potentially developed by a given system to preserve its structural configurations and functions, and suggests that the structure has the capacity to reorganize itself, creating contexts of collective, cooperative, and articulated work for perceived changes and identified challenges. “Development involves resistance and adaptation as well as growth and competition” (Jonas 2012: 268). Sustainable development, in an evolutionary dimension of permanent transformations and readjustments, cannot succeed without allowing societies to promote dynamic readaptive capacities, promoting their resilience. Resilience increases the probability of sustaining development in the future, ensuring continuity and evolution (Folke et al. 2002). Thus the intrinsic development of relationships, interactions, and adaptations, tendentially creative, allow to promote equilibria and the sustainability of the communities and territories where they are inserted, thus promoting resilient sustainability.

Summary

Resilient sustainability has a territorial application and implies collective dynamics, which on the whole presuppose to attenuate or overcome adversity, allowing the maintenance of conditions for the continuity of social organization, natural resources, and cultural values. In this context, the actions of the communities and the policies developed are fundamental to generating synergies that propel optimism and constructive attitudes toward territorial sustainability. It comprises creative actions, concerted strategies, and responsibilities between governments, local associations and sectors, investors, and the population, capable of generating involvement and synergies that promote development, respecting local identities and the environment.

Definition

Resource intensity is a quantitative method of the resources (e.g., natural resources, land, air) needed for the production process and a measure of the efficiency of resource use. It is generally expressed as a proportion of products used for value (e.g., money, quantity). Resource efficiency is a measure of production per unit of output which requires resources as an input. Resource efficiency is vital ideas for assessing dematerialization policies that are driven by efficiency (Environmental Justice Organizations, Liabilities and Trade 2019). In science economics, the main problem is resource scarcity or resource limit. There are several dimensions of resource intensity. Energy intensity is frequently used in sustainability issues. This indicator is also used to evaluate product and service energy efficiency such as equipment and buildings, cars, and

transport systems. An economy's resource intensity may alter because of a number of variables (Cleveland and Ruth 1999):

- Technical improvements and developments to produce good more efficiently
- Replacement of new materials with more desirable characteristics for older materials, e.g., input or resource substitution for production process
- Differentiated goods and services by the eco-friendly industry and consumed over time by the industry as a result of shifts between industries or shifts within industries (such as information technologies)

Introduction

Economic theory suggests that increase in a country's resource intensity provides higher growth rate. Even large volume of empirical studies indicate that resource intensity tends to hinder rather than accelerate growth rate. The link between resource abundance and underdevelopment is therefore unknown yet (Bulte et al. 2005). Potentials for dematerialization – the autonomy of resource development – describe the real growth boundaries caused by natural resource scarcity. In this sense, accounting for the resource intensity became crucial. Ever since the endeavour of Ayres and Kneese (1969) to measure material flows by the mass balance principle, to the recent Material Flow Accounting (MFA) technique, many quantitative methods are generated by academics as well as practitioners (Bithas and Kalimeris 2018). In MFA, the link between growth and natural resources is defined as the material intensity (MI) of the economy and is calculated as the amount of resources required for the one unit of good. The ratio of resources to GDP is usually referred to as the domestic material consumption (DMC)/GDP. However, DMC does not characterize the link between resources intensity and GDP as a whole. The independence of economic growth from natural resources is force-stable

under appropriate implementations. The amount of resources required to create one unit of income measures the efficiency of resource intensity in the economic process by comparing actual physical inputs (material flows) with the actual output of the production procedure (Bithas and Kalimeris 2018):

Resource intensity = Resource use/value added

Resource efficiency = Value added/resource use

where:

The resources used in the production process = the resource footprint caused by the aggregate consumption

The value added in the production processes = the price of the goods (Hertwich 2008)

According to Hertwich (2008), resource intensity can be defined across various economic units:

- Firm level: resource efficiency per output
- Product level: life cycle resource use per unit cost of the product
- Industry level: total resource use divided by the total value added
- Nation level: total resource use of a country (the sum of individual resource use) divided by gross domestic product (GDP)

In an intense competitive environment, organizations are increasingly dependent on their environment to obtain the resources they need. The degree of commitment to the resources required by the activities of the organizations in their environment is defined as resource dependence approach. In this context, resource uncertainty is one of the most important environmental challenges for organizations. Uncertainty in finding resources connotes the absence, scarcity of critical resources (Pfeffer and Salancik 2003), because the uncertainty about finding resources makes it difficult for the customer to manage mission-related activities (Macedo and Pinho 2006). At this point, the effect related to the resource intensity on the customer may occur when the firm

loses power and control against the supplier in a market with a limited number of suppliers (Fink et al. 2006). There are three elements that make up the resource uncertainty: resource intensity, resource availability uncertainty, and resource interconnectedness.

Thus, resource intensity is one of the main issues on sustainability such as sustainable growth, sustainable development, and sustainable growth goals. International economic and financial institutions develop programs and policies that focus on the resource efficiency, resource intensity, as well as resource scarcity. The issue also became hot spot in the concept of environmental and energy economics.

Summary

Resource intensity is a method for measuring the resources required for the production and disposal process. Hence, resource intensity is specified both as a measure of the efficiency of resource usage and the amount of resources involved in unit cost. Resource intensity is appointed by alterations in the mix of materials to produce individual goods and services, and the product composition of output. There are several dimensions of resource intensity. It can be defined across various economic units.

Key Issues

- Resource efficiency
- Material flow accounting (MFA)
- Biotic resources
- Fossil resources
- Mineral resources
- Land
- Water
- Air
- Health, functioning ecosystems, genetic diversity, life-support systems (Hertwich 2008)

[Firm resources approach](#); [Resource-driven view](#)

Definition

The central argument in the resource-based view (RBV) is that despite a firm having well-defined goals to accomplish, how the mission will be fulfilled is often limited by resource availability (Rangan 2004). The RBV focuses on the utilization and deployment of resources, leading to the development of resource-driven competencies and eventual competitive advantage (Prior and Glaser 2003). Resources in a firm can be either internal or external to the firm and may be acquired or already owned by the firm (Arbab Kash et al. 2014). The process through which a firm coordinates and deploys these resources will eventually affect its competitive advantage.

The RBV can be defined as:

...the identification and co-ordination of key resources, whether internal or external to the firm, tangible or intangible, and its eventual deployment to achieve firm objectives and organisational goals, in a bid to outperform competitors.

Wernerfelt's (1984) work titled "A Resource-Based View of the Firm" is considered one of the most influential papers that influenced RBV and indeed the wider body of strategy research as it explains the critical linkages between resources and output/products (Wernerfelt 1984, 1995). The author is a key seminal author in the RBV as it directs strategy scholars back toward resources as being critical to output/products and, ultimately, firm performance (Priem and Butler 2001).

Introduction

The resource-based view (RBV) is a well-established research stream within strategy research, with its origins linked to Edith Penrose's work in 1959, who gave valuable insights into the process of resource acquisition, utilization, and expansion for gaining competitive advantage (Rugman and Verbeke 2002). The central focus of attention for the RBV lies with firm-level resources (such as work force, finances, expertise, etc.) rather than the industry-level analysis favored by Porter (Green et al. 2008). The argument of the RBV is that the overarching goals of strategy are to accomplish stated firm objectives and organizational goals using often limited resources (van Nimwegen et al. 2008). The RBV also poses a counterargument to the earlier established industry-business environment-focused view of Porter, by arguing that competitive advantage can only be sustainably sourced via the development of superior capabilities (Barney 1991). These capabilities are developed based on resources available within the firm, and the utilization/underutilization of these resources will determine the direction of firm growth. In early conceptual work in strategy research, it was not uncommon to link resources to firm strengths/weaknesses and the lack of it to opportunities/threats within the competitive environment (e.g., Ansoff 1965; Andrews 1971).

The RBV also interprets responses to environmental factors and internal resource considerations during the decision-making process (Barney and Clark 2007; Hillman et al. 2009). This view of strategy suggests that companies should concentrate on the management of internal resources and find markets where these resources can be deployed to attain competitive advantage (Soosay et al. 2016). The RBV is crucial for management researchers as it assists strategists/managers in leveraging their firm's internal resources (e.g., assets, capabilities, and competencies) that hold the potential to deliver superior competitive advantages over competitors (Kraaijenbrink et al. 2010).

RBV and Strategy Analysis

A classical problem within strategy analysis is the issue of what is considered as a resource, and the RBV view takes into consideration that resources within firms are heterogeneous (Parker et al. 2015). The non-homogeneity of resources also implies that for them to be competitive in nature, they need to be valuable, scarce (rare), inimitable, non-substitutable, durable, appropriate, and organizational focused (Barney 2001; Jugdev and Mathur 2013). This concept of uniqueness in the resource base was put forward by Barney (1996) and known as the VRIO (valuable, rare, inimitable, organizational focused) framework shown in Fig. 1 below.

The framework shown above outlines how firms can move beyond just having resources to transforming it to competitiveness and improved performance (Jugdev and Mathur 2013). This framework has since grown to become an important one for strategy analysts in practice. It also details how firm resources lead to competitive advantage, with resources

translating to superior competitive advantage about its peers, leading to an increase in performance. This framework is widely regarded as the most significant theoretical framework of RBV (Newbert 2007).

While Wernerfelt’s (1984) work mostly emphasizes the link between resources and gaining business advantage (diversification, in this case), Barney (1991) provided a very detailed and formalized depiction of the business-level resource-based perspective via the VRIO framework, highlighting that organizational resources that are valuable, rare, hard to duplicate, and difficult to substitute can lead to sustained competitive advantage. The critical question when adopting the resource-based view is the question of defining what constitutes a firm’s resource. Some theorists believe that a firm’s unique capabilities in terms of technical expertise and managerial ability (intangible), while others only consider tangible assets (e.g., offices, equipment, human resources), are the key sources of heterogeneity that may result in sustained competitive advantage.

Resource-Based View, Fig. 1 VRIO framework. (Adapted from Barney 1997)

Summary

In adopting the resource-based view, it is critical to understand that a resource can be either tangible or intangible, as long as it results to distinctive competence and superior organizational routines that impact one or more of the firm's value chain functions leading to competitive advantage (Hitt and Ireland 1985). The definition presented in this study is therefore theoretically relevant to the seminal literature in the field of strategy, outlining how a firm can position itself using resources for competitive advantage within the business environment.

Accountability; Liability

Definition

Social responsibility is an ethical framework and suggests that an entity, an organization, or an individual has an obligation to act for the benefit of society.

Responsibility may refer to a lot of areas, for example (in alphabetical order):

- Collective responsibility
- Corporate social responsibility
- Legal responsibility (disambiguation)
- Moral responsibility
- Professional responsibility
- Social responsibility

There is however no agreed definition of corporate social responsibility or CSR, so this raises the question as to what exactly can be considered to be corporate social responsibility. According to the EU Commission (2002) “CSR is a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis.”

There are a lot of terms for CSR: corporate responsibility; corporate ethics; corporate accountability; sustainability; triple bottom line; and responsible business. The three main

principles upon which CSR is based are accountability, transparency, and sustainability.

Corporate Social Responsibility in the Literature

A growing number of scholars have recognized that the activities of an organization impact upon the external environment and have suggested that one of the roles of accounting should be to report upon the impact of an organization in this respect. Such a suggestion first arose in the 1970s.

Dahl states: “every large corporation should be thought of a social enterprise; that is an entity whose existence and decisions can be justified as they serve public or social purposes.”

Similarly Carroll (1979), one of the early CSR theorists, states that: “business encompasses the economic, legal ethical and discretionary expectations that society has of organization at a given point in time.”

The idea of social responsibility is a theory in which everyone in society must fulfill their civic duties. It means that the actions of each person in any given society should be motivated by a desire to benefit society as a whole. Social responsibility is founded on a system of ethics, in which any decisions made, or actions taken, should be ethically considered. Undertaking an action or decision that is harmful to society or the environment in any way would be considered socially irresponsible. Social responsibility is a duty every individual has to perform so as to maintain a balance between the economy and the ecosystems. Social responsibility therefore means sustaining the equilibrium between the two. It pertains not only to business organizations but also to everyone whose any action impacts the environment.

Like affirmed by Vallaey (2011), social responsibility, a new core responsibility that complements moral and legal responsibilities, is a collective, not a personal, responsibility that fosters political creativity. CSR is the way firms integrate social, environmental, and economic concerns into their values, culture, decision-making, strategy, and operations in a transparent and

accountable manner and thereby establish better practices within the firm, create wealth, and improve society. The World Business Council for Sustainable Development describes CSR as the business contribution to sustainable economic development.

Corporate social responsibility (CSR) first appeared in the 1960s and has since been embraced by an ever-increasing number of organizations worldwide (Carroll 1991). According to Carroll (1983), “corporate social responsibility involves the conduct of a business so that it is economically profitable, law abiding, ethical and socially supportive. To be socially responsible then means that profitability and obedience to the law are foremost conditions when discussing the firm’s ethics and the extent to which it supports the society in which it exists with contributions of money, time and talent” (p. 608).

Furthermore, attempts have been made to determine the rationales behind firms engaging in the CSR efforts and its components.

Initially, shareholders were considered the only stakeholders. Nobel Laureate Milton Friedman (1970) said: “the business of business is business,” and “the only social responsibility of business is maximizing profits.” Gradually companies grew in size and clout and started playing ever-increasing role in society. This led to redefining stakeholders. Today, society at large, customers, vendors, employees, government, etc. are considered as much stakeholders as shareholders. Business uses scarce resources of society and often adversely affects environment; islands of plenty cannot exist amidst oceans of poverty; problems are too vast and complex; government efforts need to be supplemented by business; and social and environmental problems can threaten the survival of business (Lalit, J., Senior Vice President & Company Secretary, Jubilant Life Sciences Ltd., in a presentation of the theme dedicated to corporate social responsibility in 2013).

Existing research drew on different theories to explain the CSR phenomenon, including stakeholder theory, agency theory, legitimacy

theory, and institutional theory (Frynas and Yamahaki 2016). Under the stakeholder theory (Freeman 1984), firms incorporated CSR in their operations largely because of stakeholders’ pressure. Belkaoui and Karpik (1989), based on the agency theory, posited that image building and public perceptions dictate managers’ expenditure decisions on the social causes. Reverte (2009) used combinations of theories to study the CSR phenomenon. For example, the stakeholder theory was used in conjunction with the agency theory to explain the determinants of CSR. Frynas and Yamahaki (2016) noted that multi-theory studies enhanced the understanding of CSR. Stakeholder theory is one approach to the managing of an organization. It is particularly important for an understanding of CSR and its incorporation into organizational activity.

Regardless of the theories, the CSR components proposed in the previous publications are basically aligned. Specifically, several pioneering studies developed CSR indices based on Carroll’s (1979) four themes of social responsibilities: economic, legal, ethical, and discretionary. The discretionary responsibility was later replaced with philanthropic responsibility (Carroll 1991).

Carroll (1991) considers that social responsibility of business firms includes economic, legal, ethical, and philanthropic responsibilities to the society in which the firm belongs. Carroll’s CSR hierarchy places the economic responsibilities in the first priority followed by the legal and ethical responsibilities and finally the philanthropic responsibilities.

In 1991 Carroll first presented his CSR model as a pyramid. He once again his original historical explanation for the relative weighting, saying: “To be sure, all these kinds of responsibilities have always existed to some extent, but it has only been in recent years that ethical and philanthropic functions have taken a significant place” (p. 40) (Fig. 1).

The pyramid of corporate social responsibility gives us a “framework for understanding the evolving nature of the firm’s economic, legal,

Responsibility, Fig. 1 The pyramid of corporate social responsibility (Carroll 1991). Philanthropic responsibilities: Contribute resources to the community; improve quality of life; Ethical responsibilities: Obligation to do what is right, just, and fair; avoid harm; Legal responsibilities: Law is society’s codification of right and wrong. Play by the rules of the game; Economic responsibilities: The foundation on which all other rest

ethical, and philanthropic performance” (Carroll 1991, p. 47).

Additional CSR components were later developed following a guideline by Global Reporting Initiative (GRI).

Global Reporting Initiative (GRI) is an organization that provides a framework for sustainability reporting. This framework can be used by all types of organizations.

Although the GRI is independent, it remains a collaborating center of United Nations Environment Programme (UNEP) and works in cooperation with the United Nations Global Compact.

Sustainability reporting is the action where an organization publicly communicates their economic, environmental, and social performance. The GRI’s mission is to make sustainability reporting by all organizations as routine and comparable as financial reporting. GRI Guidelines are the most widely used in the world for reporting. More than 4,000 organizations from 60 countries use the Guidelines to produce their sustainability reports. The GRI Guidelines provide a holistic framework that addresses broad performance – social, environmental, and

Responsibility, Fig. 2 Elkington (1997), 3 P and sustainability

economic – as to how an organization is reporting to stakeholders. GRI is used widely internationally as a generally accepted reporting framework and, as such, provides a method for increased comparability.

In a nutshell, the stakeholder theory (Freeman 1984) was most frequently used in CSR studies, followed by institutional theory (Scott 2001) and legitimacy theory (Suchman 1995).

Moreover, the authors classified the theories with respect to CSR practices into the external- and internal-driver groups. The stakeholder theory, institutional theory, legitimacy theory, and resource independence theory (Pfeffer and Salancik 1978) belong to the external-driver group, while the internal-driver group includes the Edith Penrose’s resource-based view (Lockett and Thompson 2004) and Jensen and Meckling’s (1976) agency theory (Carroll).

Another interesting model has been coined by John Elkington in 1997, like presented in the Fig. 2.

The term coined by famous author John Elkington in his book *Cannibals with Forks: The Triple Bottom Line of 21st Century Business*, published in 1997.

He espouses seven dimensions of revolutions taking place that would necessitate looking at triple bottom line:

Markets – increasing competition.
 Values – shift from “hard” commercial values to “softer” triple bottom line values.
 Transparency – business is finding its activities under increasing scrutiny.
 Life cycle performance – scrutiny of entire life cycle process of the product: from raw material stage to discarding stage.
 Partnerships – compulsion to align with others in synchronization with triple bottom line principles. Time – growing importance of working on real-time basis.
 Corporate governance – the need to satisfy all stakeholders.

He propounds that the three prongs of the fork constituting triple bottom line are economic prosperity, environmental preservation, and social justice.

In order to evaluate a business, apart from economic results, which are normally made available, we should also evaluate the contribution made toward environment and society. Another similar term coined by same author is 3P (people, planet, and profits).

Summary

The work examines social responsibility. After the definition of the theme, CSR is analyzed remembering the most known literature. Among the many existing models, the work presents the pyramid of corporate social responsibility of Carroll (1991) and the model of the 3P of Elkington (1997). Moreover, for completeness, it introduces GRI, like the organization that provides a framework for sustainability reporting.

[Chemical sector commitment program](#); [HSE program for chemical sector](#)

Description

Responsible Care[®] has been the global chemical sector performance initiative for the last 30 years and it is currently implemented by 62 chemical associations in nearly 70 countries around the world (ICCA 2018). It is a global chemical industry voluntary initiative.

The Responsible Care[®] program reflects also the industry's effort to reach the WSSD 2020 goal established during the World Summit on sustainable development, held in Johannesburg in 2002, that "chemicals are used and produced in ways that lead to the minimization of significant adverse affects on human health and the environment" (Ganzleben et al. 2013).

Responsible Care program's actions include also cooperation with UN environment, distributors, governments, and regulators, as well as accelerating progress towards the UN sustainable

development goals (SDGs) (see ► ["SDGs"](#)) by 2030 in the area of health and wellness (UN 2019). Product stewardship is a fundamental component of the Responsible Care[®] initiative and includes the risk evaluation and the development of actions for reducing the possible consequences to human health and the environment related to those risks.

The commitment of the global chemical sector to reduce environmental impacts and risks for human health is an ongoing process and together with Responsible Care, many other initiatives have been implemented.

For instance, in February 2006 in Dubai, the first International Conference on Chemicals Management (ICCM1) adopted the Strategic Approach to International Management (SAICM), a framework for global chemicals management.

Introduction

The chemical sector has always been considered, in the common thought, the most dangerous and impacting industry in regards of the natural environment and human health. It is not so unusual to read on the news about accidents or near misses happened in chemical plants around the world, followed by uncontrolled toxic chemicals release and/or intense fires and/or explosions. More than 25,000 chemical industrial accidents have been recorded in the world in the past 90 years (FACTS 2019). Some of these accidents have become famous due to the severe or persistent effects on the workers and the local population in terms of health injuries and/or environmental contamination. One of them is the accident occurred in Seveso (Italy) in 1976, during which a toxic cloud containing dioxin was released in the environment, causing very long consequences to human and animal health in the area (HSE 2019). Some years after the Seveso disaster, the European Commission enacted the Directive 82/501/EC, aimed at improving the safety of sites containing large quantities of dangerous substances, known as the "Seveso Directive." The main aspect of the directive and the following laws regards the necessity to prevent accidents

and impacts through a good integrated system which aims at assessing risks (see ► [“Risk Management”](#)), preventing risky situations, and managing emergencies.

Chemical Sector Commitment Towards Sustainable Development

Chemistry can be considered either as science or as industrial sector and it covers a fundamental role to reach the goals of sustainable development. Chemical products are in fact either final products or raw materials for many other downstream manufacturing industries. Through continuous innovation and performance improvement in processes, technologies, and products, the chemical sector can provide more sustainable solutions to its customers, who are other industries as well as final consumers. That is why its full involvement and commitment is so important in the process for sustainable development.

The topic of sustainability is not new to the chemical sector as the Responsible Care (RC) program was born in Canada in 1984 by CCPA (Canadian Producers Association), 3 years before the official definition of sustainable development was given by Brundtland. In 1989 the program was launched in Europe by CEFIC (European Chemical Industry Council) and then adopted by single countries (Belanger et al. 2009). Since the launch of the program, chemical industrial associations as well as single companies around the world have implemented many initiatives and addressed to reduce the negative effects on environment and human health connected with the extraction, manipulation, process, use, and disposal of chemical substances.

RC promotes behaviors oriented to safety, health, and environment within the more general framework of corporate social responsibility (CSR) (see ► [“CSR”](#)). At the beginning the RC program committed the companies to improve continuously their performances through an integrated management system of safety, health, and environment. Over the years, the RC program has enlarged in

order to cover the sustainable management of products along their whole life cycle (product stewardship) (see ► [“Product Life Cycle”](#)). Product stewardship (PS) has then become a pillar in the RC program; it can be considered as the practice of making health, safety, and environmental protection an integral part of the life cycle of chemical products (ICCA 2007).

Together with PS, companies have to take into account in their strategies also their social responsibility. The guarantee of the safety and health of employees and all those who, at any title, work or are located in the chemical sites is the first commitment of the Responsible Care program towards the social dimension of sustainability. The strategic vision of any company which adheres to RC program has to be based on continuous improvement of the quality of places of work and overall well-being of employees.

Each company that decides to be part of the RC initiative has to sign the Responsible Care Global Charter, which was published in 2006 and revised in 2014 by ICCA, and in this way commits to dedicate its people, technologies, and business practices to six key elements, reported below (ICCA 2019):

1. Proactively support safe chemicals management
2. Safeguard people and the environment by continuously improving our environmental, health, and safety performance; the security of our facilities, processes, and technologies; and by driving continuous improvement in chemical product safety and stewardship throughout the supply chain
3. Strengthen chemicals management systems by participating in the development and implementation of lifecycle-oriented, sound science and risk-based chemical safety legislation, and best practices chemicals management systems
4. Influence business partners to promote the safe management of chemicals within their own operations
5. Engage stakeholders, understanding, and respond to their concerns and expectations for

safer operations and products, and communicate openly on our performance and products

6. Contribute to sustainability through improved performance, expanded economic opportunities, and the development of innovative technologies and other solutions to societal challenges

All signatories to the Responsible Care Global Charter make a commitment to continuously improve their performance and also report on their progress. Companies have to collect and report data for a core set of environmental, health, and safety (EHS) (see ► [“Health and Safety”](#)) performance measures (ICCA 2019).

The commitment to Responsible Care program is made through a constructive dialogue based on concrete facts, with clear indicators, which demonstrate the continuous improvement of company performances towards environmental, health, and safety protection along the whole life cycle of their products.

Responsible Care[®] initiative is an essential part to the wider strategic approach to international chemicals management (SAICM). As a result of a long process of negotiations among governments, nongovernmental organizations and other stakeholders within the framework of the preparatory committee for the development of a strategic approach to international chemicals management, the first session of the International Conference on Chemicals Management (ICCM1) took place in Dubai in 2006. This step was taken in response to the endorsement taken in 2002 at the World Summit on sustainable development in September 2002, for the development of a strategic approach to international chemicals management (SAICM) (SAICM/ICCM 2006). During this conference, the chemical industry was represented by the international council of chemical associations (ICCA) which introduced the global product strategy (GPS) (SAICM 2006). The product stewardship under GPS and the Responsible Care[®] Global Charter are industry's voluntary initiatives that contribute to SAICM implementation.

Since its birth in 2006, GPS has supported industry to build on its product stewardship actions through the value chain. It provides an instrument to share best practices and information about chemical safety, with the following objectives (ICCA 2011):

- Enhance product stewardship worldwide
- Improve chemicals management through risk assessment and risk management
- Enhance transparency about chemical substances and products
- Reduce differences in the safe handling of chemical substances between developing, emerging, and industrialized countries

ICCA provides GPS guidelines, but each company has to modify the program according to the own experience and capacity, as well as the specific context and market where it acts, in order to implement specific strategies which address health and safety, process safety, pollution prevention (see ► [“Pollution”](#)), and all the elements that are necessary to achieve the sustainability goal.

Summary

In the past 30 years the chemical sector has made significant steps forward to reduce its negative impact on the environment, to reduce the risks associated with the use of chemical substances, to prevent damages to local populations and workers, and to construct a common trust and change the common perception in its regards. The Responsible Care[®] initiative represents the global commitment made by the chemical sector towards all the stakeholders. Companies which commit to Responsible Care[®] program do not limit themselves to consider the people who are inside their production and logistics sites, but the general aim is to demonstrate to all the stakeholders, and in particular to local communities, that industrial chemical activities can represent a significant opportunity for development in a sustainable manner.

Responsible Consumption

Adriana Paliwoda-Matiolańska
Cracow University of Economics,
Kraków, Poland

Synonyms

[Alternative consumerism](#); [Conscious consumerism](#); [Conscious consumption](#); [Ecological consumption](#); [Environmental-friendly consumption](#); [Green consumption](#); [Socially responsible consumerism](#)

Definition

Responsible consumption is both an ideology and a form of social movement that promotes the idea of a rational, economic, self-aware consumer who can adjust and limit its expectations and needs to serve common good through consumer behavior. It focuses not only on consumer rights but also on consumer obligations and has three dimensions: rational consumption, ethical consumption, and consumer activism.

Both historical and modern perspective consumptions play a vital role in supporting human existence. That is why its form is so crucial for human and social group development. However, studies and modern trends show that the contemporary style of consumption harms society, nature, and human psychology. Besides present consumptions, patterns are not justified by real needs, negating social, ecological, and spiritual costs. Contemporary consumption attaches importance to goods that exceed the utility value of it, but it determines the identity and status of the buyer. In highly developed countries, it takes the form of hyper-consumption very often accompanied with *affluenza* that brought criticism of contemporary consumerism (among others, Veblen 1994; Fromm 2007; Bauman 2001; Baudrillard 2006; Ritter 2009; Barber 2009; Aldridge 2006) and created the

necessity of searching for alternative consumption patterns.

Responsible consumption is both an ideology and form of social movement based on the desire to reconcile citizenship and consumerism. The idea shapes the vision of a rational, economical, self-aware consumer who can adjust and limit its expectation and needs to serve common good. The roots of responsible consumption are located in the consumer rights movement, but the idea itself is evolving. Its meaning and essence were extended by other social movements like, for example, the human rights, the civil rights, the women's right, the environmental protection and conservation, the animal rights and welfare, the transparency and anti-corruption movements, and science development. Responsible consumption became a positive example of citizens regaining sovereignty over-consumption. Through the act of consumption, the contemporary consumer determines his position in the field of social matters and other problems of a political or economic nature of the modern world. It is an active form of public control over business activities in times when we can observe the weakening of the regulatory role of national governments toward international corporations as a result of globalization processes. Unlike traditional consumer protection movements, it focuses on legitimizing the consumer's position as sources to achieve social goals and to protect the interests of both consumers and citizens. It creates a vision of the dominant consumer who through purchasing process expresses support or opposition toward social or environmental issues rather than creating pressure on the government. Its primary objective is to strengthen the position of consumers who, through responsible and prudent decisions, develop a form of collective force by defining the accepted nature of the commodity and its type of sale.

Responsible consumption focuses not only on consumer rights but also on consumer obligations. The powers are the ability to meet your own needs, choose, and state own opinions and access to information and consumer education. Responsibilities focus on using consumer power in the market to eliminate fraud and actions detrimental to consumers, as well as strive to support ethical purchasing behavior

Responsible Consumption, Fig. 1 Responsible consumption. (Source: Own elaboration)

and support patterns of sustainable production and consumption. The evaluation of products or services is based on the degree of meeting the expected value of both personal and social character. The responsible consumer purchases goods that are socially responsible, environmentally friendly, and produced with compliance to ethics standards. On the other side, he/she avoids products that do not meet these requirements, boycott such goods, and express the opposition. Therefore we can distinguish three main dimensions of responsible consumption: rational consumption, ethical consumption, and consumer activism (Fig. 1).

Rational consumption has three elements: biological, economic, and social. The biological aspect of consumption describes levels of utilization of food and nonfood product sufficient for living. The economic character is based on cost calculation and the optimal allocation of resources for maximizing consumer utility. Social aspects addressed the impact of the consumption processes over society.

The ethical perspective of responsible consumption comes out as a result of market trends and changes in consumer behavior, as so the evolution of moral standards like the rise of environmental ethics. We can distinguish five areas of purchasing behavior that allow segmentation of ethical consumers: (1) healthy food (with emphasis on organic food), (2) goods locally produced and supplied, (3) fair-trade products, (4) animal welfare, and (5) environmental friendly. It is expressed both in positive consumer behaviors – supporting the product as mentioned in earlier groups, as well as negative

ones based on negating and boycotting products, brands, and enterprises that ignore the features discussed above.

The third part of responsible consumption is consumer activism that means active participation in shaping consumer reality through participation in demonstrations, sending petitions or protests, and supporting NGO and social organizations connected with environmental and social issues alight with a consumer boycott.

Summary

In a consumer society, consumption plays a significant economic but also a culture-forming role. The concept of responsible consumption refers to its cultural significance emphasizing its impact on the surrounding reality. Responsible consumption uses market economy mechanisms, both on the demand and supply side, in the interest of citizens and the public good. Expanding the sphere of factors shaping purchasing decisions by social, ecological, and moral aspects, the consumer can more effectively influence the environment. With the contemporary dominance of the economic paradigm over the others, growing social awareness and a sense of shared responsibility for the local, regional, or global environment of consumers allows expanding the impact of consumer decisions on the economic sphere, including business behavior. On the other hand, responsible consumption based on a philosophy of life and consumption that is more environmentally friendly changes the value system. Moreover, it has an impact on how pressure on the social and natural environment does not exceed its capacity to support sustainability.

Responsiveness

Francesca Gennari
Department of Economics and Management,
University of Brescia, Brescia, Italy

Synonyms

[Accountability](#); [Responsibility](#); [Responsible governance](#); [Responsible government](#); [Social responsibility](#); [Stakeholder Engagement](#)

Definition

Responsiveness refers to the ability of public administration and private firms to be accountable toward stakeholders about their ability to achieve their interests and expectations. The concept of responsiveness is strictly connected with the

concept of responsibility; this last referred to the motivations that lead an organization to use resources in the interest of the resources' owners.

Since the 1980s of the last century, the reform movements in the public sector emphasized the importance to overcome the mere compliance to formalized processes and procedures toward a more citizens' need- and expectation-centered approach.

Also in the private sector, the debate about social responsibility starting in the 1960s of the last century has resulted in the belief that responsiveness is not limited to the communication activities by companies, but it expresses the global corporate responsibility that is leading the business according with the awareness of stakeholders' expectations and their engagement in activities and strategies.

Therefore, the spread of concepts as social responsibility and sustainability induces a new way to interpret both the organizations' responsibility, embracing economic, social, and environmental impacts of their actions, and the organizations' responsiveness, moving from the capability to response to external pressures and expectations to a more proactive approach as the stakeholder engagement.

Introduction

Many scholars and practitioners paid attention to the principle of responsiveness both in public and private sector, and this concept developed during the past until now together with the concept of responsibility. Responsiveness is essential for a responsible government or governance, but the concept differs from that of responsibility (Brummer 1991): the first refers to the accountability for organization's actions, while the latter refers to the motivation of those actions.

In the public sector, responsiveness is a prominent theme in the literature of public administration and refers to the effort made by a government agency to be accountable about its ability to provide services to the public.

At first, responsiveness was limited to the communication of the execution of specific

government tasks, according with a bureaucratic point of view; then the concept expanded including the ability by government to satisfy broader interests referring to citizens' expectations and to achieve goals in an effective way using efficiently the public resources. Today the principle of responsiveness widens its meaning concerning the ability to achieve a public interest that is not merely an aggregation of individual interests and emphasizing the engagement of all social players (government, citizens, private organizations, and so on) who collaborate together for the interests of all of them. In this sense, according to Dahl (1971), responsiveness is at the base of democracy.

Also in the private sector, the principle of responsiveness evolved together with the one of responsibility. Responsiveness is the organization's response to stakeholders' issues which affects its sustainability performance, and it is realized through decisions, actions, and performance, as well as communication with stakeholders. The observation of corporate responsibility according with a global point of view, including different dimensions (economic, social, and environmental ones) for sustainable success in the long run, implies a new way to interpret responsiveness. In fact, it is not limited to the communication toward stakeholders, but it is a way to lead the business according with the awareness of stakeholders' expectations and their active engagement in corporate activities and strategies.

Theoretical Framework

In the public sector, the principle of responsiveness is related to the main theories characterizing the administrative issue.

The "classic public administration theory" was founded in the latter part of the nineteenth century upon the conviction that precise prescribed rules were powerful instruments for the economic development and the building of modern states (Bresser and Luiz 2007). The role of bureaucratic authority structures in facilitating economic growth has been a sociological concern since

Max Weber's classic contributions almost 100 years ago (Evans and Rauch 1999). The public organizations had to be accountable to constituents about their ability to execute their task in a compliant and impartial way (Kernaghan and Langford 1990).

The reform movements since the 1980s of the last century have been driven in large part both by the requirement that governments respond to the changes in the international economic system and by the demands for government services and regulations in national political systems. In this context, two main lines of thoughts about public management developed (Aucoin 1990).

The first one is inspired by the "public choice theory" (Buchanan and Tullock 1962; Niskanen 1971), which aims at understanding the public administration with the usual economic tools, focusing on the need to re-establish the primacy of representative government over bureaucracy. In this respect, the responsiveness of politicians is the capacity to ensure that the broader interests in public policy are reflected in what is decided, avoiding the achievement of narrow self-interests by special groups (Aucoin 1990).

The second line of thought, the so-called "managerialism" (Peters and Waterman 1982) refers to the need to re-establish the primacy of managerial principles over bureaucracy, focusing on the capacities by organizations to realize their goals by means of management structures and processes. In this case, the use of the word "management" aims at emphasizing the importance of the effective and efficient use of the resources, according with the organization's objectives and the laws' requirements, in contrast with the word "administration" intended as the mere compliance to formalized processes and procedures. The managerialism paradigm gives priority to the responsiveness of politicians to their constituencies, by means of consultations and communications (Aucoin 1990).

The "New Public Management" (NPM) theory (Osborne and Gaebler 1992; Osborne and Plastrik 1997) takes its intellectual foundations from public choice theory and from managerialism (Bourgon 2007). This line of thoughts is based

on some pillars, as the citizen-centered approach and the creation of value by resources.

Citizen-centered approach means that the role of the citizens is not reduced to that of a customer or a mere user of government services, but it recognizes the citizens' rights and interests. In other words, this means that the need of public interest should be reconciled with the need to be responsive to citizens' needs and expectations.

With regard to value creation, NPM's approach focuses on the results and performance, emphasizing the importance of an effective and efficient use of the resources in the interests of citizens. Considering that it could be difficult for individuals determining the quantity and quality of services corresponding to the resources given in the form of taxes, the governments should be responsive to citizens in this regard. This behavior favors the creation of relations of trust and consensus between the state and its citizens, nurturing a virtuous cycle between resources and performance, this last expression of the correct use of resources.

Nowadays, the environment is even more complex because of the effects of globalization, the emergence of new global economic engines, the impact of information technologies, and the interconnected roles of private sector, public sector, and civil society institutions. In this context, also the concept of public interest evolves from the aggregation of individual interests to the common (or shared) interests of citizens (Bourgon 2007). The government should be responsive about its role, that is, the capacity to articulate and realize this public interest (e.g., ensuring that services are accessible to all entitled to these, that communications are comprehensible, and that resources are used according with a sustainable vision).

In the private sector, the principle of responsiveness is strictly connected with the concept of corporate social responsibility (CSR).

CSR has been evolving for decades (Mosca and Civera 2017). The debate started in the 1960s of the last century with Friedman, who stated there is one and only one social responsibility of business, that is, to use its resources and engage in activities designed to increase its profits

so long as it stays within the rules of the game, engaging in open and free competition without deception or fraud. According with Friedman's thought, the responsibility of managers is to conduct business in accordance with owners' desires, which generally are to make as much money as possible, while conforming to their basic rules of the society, both those embodied in law and those embodied in ethical custom. Therefore, the managers are the agent of the individuals who own the corporation, and their primary responsibility is to them.

McGuire (1963) confirms the primacy of economic concerns, but he starts to outline a concept of social responsibility as company's responsibility toward society, which extends beyond the economic and legal obligations. Manne and Wallich (1972) demand the freedom in behavior for social responsibility.

Ackerman and Bauer (1976) criticize the use of the word responsibility, this last being connected with the process of assuming an obligation, placing emphasis on behavior's motivation. They prefer talking about social responsiveness, that is, the ability to respond to social demands. In other words, they focus more on the result or performance as a response to demand than on the motivations of this response. Sethi (1975) also notices a difference between social responsibility and social responsiveness: in the author's opinion the first is about a behavior coherent with the prevailing social norms, value, and expectations, while the last is about the ability to respond to social pressures in a anticipatory and preventive manner.

In summary, the attempts to define social responsibility focused on the freedom of behaviors (responsibility) or on the manner of response (responsiveness).

Carroll's four-part definition of CSR was originally stated as economic, legal, ethical, and discretionary (philanthropic) expectations that society has toward organizations (Carroll 1979, 1991). These dimensions help to frame the nature of business' responsibilities to the society of which it is a part. Organizations can refer to different mode or philosophy to manage these responsibilities responding to social issues

(social responsiveness) with a reaction approach or proactive approach (Wilson 1974). Being responsive enables organizations to act on their social responsibilities without being bogged in the definitional problems that occur when organizations try to get a precise fix on what their true responsibilities are before acting (Carroll 1979). In other words, while corporate social responsibility has ethical or moral threads, corporate social responsiveness has no moral or ethical connotations but is concerned only with the managerial processes of response.

Many models were developed for assessing individual organization responsibility (Tuzzolino and Armandi 1981), and systems approaches were created to understand the mechanisms of response (Preston and Post 1975). According to Salbu (1993), the different models of responsiveness used for the implementation and evaluation of CSR programs may even affect the substance of the CSR content.

The responsiveness is a key concept in stakeholder engagement model. According to Freeman (Freeman 1984; Freeman and Dmytriiev 2017), organizations have a wider obligation to consider the effects of their actions on group of people who qualify as stakeholders, influencing and influenced by corporate behaviors, and have to act transparently in this regard.

The Accountability Principles (2018) define responsiveness as the way an organization responds to material sustainability topics and their related impacts on its external and internal stakeholders. An effective response is aligned with the organization's objectives and integrated into its strategy including decisions, actions, and performance, as well as communication with stakeholders.

Responses may include establishing policies, objectives, and targets, enhancing governance structures, developing or advancing management systems and processes, developing or implementing action plans, engaging stakeholders, measuring and monitoring sustainability performance and impacts, reporting, issuing communications, and/or achieving assurance.

It follows that responsiveness is not limited to the communication activities toward stakeholders,

but it is a way to lead the business according with the awareness of stakeholders' expectations and their engagement in activities and strategies. In other words, it expresses the global responsibility that a company has toward its stakeholders and that consists in the ability to understand and satisfy stakeholders' expectations in the long run, minimizing risks and catching opportunities (Salvioni et al. 2016; Gennari and Salvioni 2018). With this regard, Gorenak and Bobek (2010) discussed the "total responsibility" management, which sets up processes and business models that are responsible and sustainable at their core, involving goals, strategies, and operational actions.

Key Issues

In both public and private sector, the concept of responsiveness developed during the decades starting from the capability to response to external pressures and expectations to the proactive approach characterizing the stakeholder engagement.

In the public sector, organizations use an approach called "citizen participation or engagement" to ensure that they will not lose sight of their stakeholders' needs. The most prominent and effective form of citizen participation involves bringing citizens into the agency as decision-makers, also using ICT in an innovative way (e.g., e-participation). Responsiveness, together with accountability, can move governments from reform to transformation to meet the challenges of implementing the UN 2030 Agenda.

The same happens in the private sector, with the emphasis on the concept of inclusivity that is the participation of stakeholders in developing and achieving an accountable and strategic response to the sustainable development of the organization (AA1000 2008). Stakeholder engagement is the tool that organizations use to help them achieve inclusivity (AA 2015). An inclusive organization accepts its accountability to those on whom it has an impact and who have an impact on it. Inclusivity is about engaging at all

levels, including at the level of the organization's governance, to achieve better outcomes.

Summary

The principle of responsiveness is developing over and over again, according with the changes in the social and economic environments.

Modern public administration involves a tension between a better responsiveness to citizens and an effective collaboration with them as partners, losing the benefits of considering these values in an integrated way (Vigoda 2002). Collaboration is founded on responsiveness, but it reaches beyond. Collaboration means negotiation, participation, cooperation, mutual understanding, and a more equitable distribution of power and resources. Scholars focused attention on the responsibilities of public administration in its interaction with citizens but paid less attention to the active roles of citizens and to their obligations in the community (Lynn 1998; Pollit and Bouckaert 2000). The relationships between public administration and citizens develop long a continuum that ends to a new generation step characterized by a rational and applicable level of integration across all social players (including media, academia, private sector, etc.) (Vigoda 2002).

In the private sector, the link between responsiveness and responsibility stresses the risk management, that is, the management of the relation between the ability to respond and the risk reduction. The approach of sustainable development in the long term implies that corporate goals and strategies consider a new type of value generated by risk reduction and the exploitation of opportunities, thanks to the constant and bidirectional relations with stakeholders, that is, the stakeholder relationship management (Salvioni and Gennari 2017). In fact, from a risk management perspective, the benefits of stakeholder engagement include higher levels of trust with stakeholder groups, stakeholders' contribution to decision-making processes affecting their future, the better understanding of risks, and opportunities both by company and stakeholders themselves.

A stakeholder orientation demands that organizations seek and involve risk stakeholders in the risk management process. The level of involvement will depend on both the identified risks and how stakeholders are expected to be affected by the proposed solutions and decision-making processes (Ndlela 2019).

Strategic responsiveness is the ability to assess environmental change and mobilize firm resources around responsive actions taken to adapt the firm to new challenges in the environment (Andersen et al. 2007), and it includes the capability to observe, react, and adapt to prior and emerging risks.

This ability allows company to compete in a globalized world characterized by growing competition to obtain approval and resources from significant stakeholders, changing the premises for corporate success (Brondoni 2014), which depends on the capability to create shared value (Porter and Kramer 2006; Porter and Kramer 2011). In this sense, responsiveness becomes a tool to identify and manage risks of relations with stakeholders and a basis for the creation of a sustainable positioning of companies in the long time.

Reverse Innovation

Abhijit Roy

Department of Marketing, Howard University,
Washington DC, USA

Synonyms

Disruptive innovation; Social innovation; Sustainable innovation; Trickle-up innovation

Definition

Reverse innovation is also referred to as trickle-up innovation and takes place when it is first used in a developing world before moving to more developed countries. The term was first used by *Dartmouth* Professor Vijay Govindarajan and Chris Trimble and *GE*'s Jeffrey R. Immelt in a *Harvard Business Review* article published in 2009 (Immelt et al. 2009). Govindarajan and Trimble later elaborated on the phenomenon in a book, *Reverse Innovation: Create Far from Home, Win Everywhere*, published by the *Harvard Business Press* in 2012 (Govindarajan and Trimble 2012). It involves a process whereby products made as inexpensive models to meet the needs of developing markets with limited infrastructure are later sold as low-cost innovative goods for developed markets.

Introduction

The traditional path of globalization of products involves firms removing expensive features from their established product and selling the defeatured products in the developing world. This approach often times does not directly meet the needs of such markets and is targeted mostly at the affluent segments in these markets. The case for reverse innovation arises when a need or requirement for low cost products arise in one or more developing countries (Govindarajan and Ramamurti 2011). Once the product has been

successful in these markets, they are sold in the developed world with a few upgrades – including the West – at lower prices, which creates new markets for these innovations (Ostraszewska and Tylec 2015).

The term was originally defined as “innovation blowback” by Hagel and Brown (2005), where they predicted that the periphery of today’s global business environment had the highest potential of success. Most of the unmet needs of the world were at the borders of companies, markets, industries, geographies (Corsi and Di Minin 2014), intellectual disciplines, and generations. They saw these areas where the customer needs were unmet and where disruptive innovations had the greatest chances of success.

As shown in Fig. 1, historically multinational corporations from developed countries introduced new products in their own countries before selling them to emerging markets. In reverse innovation, a product is initially developed to meet a need in the developing world and later finds a market in the developed world.

The industries where reverse innovation is widely used is first discussed, followed by a proposed typology of reverse innovation focusing on cases when most of the innovation is taking place in the developing countries (also referred to as “Reverse Innovation in the Strong Sense”) versus conditions when only one of its key innovative capabilities takes place in a developing country (also referred to as “Reverse Innovation in the Weak Sense”). Finally, the caveats of the practice are discussed.

Industries Where Reverse Innovation Is Prevalent

Reverse innovation has the potential of transforming several industries, including banking, consumer products, energy, healthcare, technology, and transportation among others. Some examples within each industry are as follows:

Banking: The banking industry in developing countries had ignored the low end of the market for a long time before the 2006 Nobel Peace winner, Muhammad Yunus, founded

Reverse Innovation,

Fig. 1 Contrasting traditional with reverse innovation

Bangladesh's Grameen Bank, unleashing the microfinance revolution, which has found global acceptance, including in impoverished neighborhoods in developed countries. The microcredit banking model is now used in over a hundred countries around the world.

Consumer products: Proctor and Gamble (P&G) used a honey-based cold remedy created in Mexico later in more profitable markets in Europe and the United States. Nestle sold its low-fat, low-cost dried noodles originally created for rural India as a healthy alternative in Australia and New Zealand (Agnihotri 2015). Gatorade, the most popular energy drink throughout the world, traces its origins to scientists trying to keep cholera patients hydrated in Bangladesh in the 1960s. Chicken Tikka Masala, the number one food in the United Kingdom, traces its origins back to India.

Energy: Most of the developing world lacks access to the electric grid. As the infrastructure is built, renewable energy will be more central to these countries' solutions. For example, by 2030, the proportion of India's energy derived from solar and wind power will be as much as five times greater than the proportion of the United States. Where these two resources are inadequate, natural gas-powered or biogas powered turbines that are less than one-hundredth of those used in the wealthy world (Govindarajan and Trimble 2012). These energy alternatives have the potential of future use in the developed world.

Healthcare: GE built an ultra-portable electrocardiograph machine for doctors in India so that they could carry it easily from village to village (Ahmed et al., 2017). The low-cost machine later found a market in the United States and other advanced countries at a substantially lower price than existing electrocardiograph machines (Bhatti et al. 2017). Other blocks of the healthcare systems such as service delivery, health information, health financing, and health leadership and governance from the developing world are gradually finding usage in the developed countries (DePasse and Lee 2013; Tran and Ravaud 2016). Yoga, first introduced in India, has now found a home throughout the world including Western countries (Kumar and Aanand 2016).

Technology: Nokia is testing new business models on mobile phones for classified ads in Kenya which has a potential of being transferred to advanced markets in the future. It has already created new features in its handheld phones in the United States, based on observations of how phones are shared in Ghana. Microsoft is creating new phone app services for regular mobile phones which allow users with access to web sites such as Twitter and Facebook (Agarwal and Brem 2012). Primarily built for low-cost markets in India and South Africa, there is a strong potential for these apps in developed markets as a low-cost cloud computing platform.

Transportation: Tata Motors created a very basic car for less than \$2,000 for the Indian market

called the Nano. In 2009, an upgraded version was sold in Europe as the Tata Europa. The long-term goal was to compete in the low end of the market with leading automotive manufacturers. A team of MIT engineers designed the Leveraged Freedom Chair (LFC), which is 80% faster and 40% more efficient than a conventional wheelchair. It sells for approximately \$250 on par with the price of wheelchairs in developing countries. The technologies that generate its high performance and low cost have been incorporated into a Western version, the GRIT Freedom Chair and sells for \$3295, which is less than half the price of competing products in the United States.

A Typology of Reverse Innovation

Von Zedtwitz et al. (2015) offered a typology of reverse innovation. Considering four sequential phases of concept ideation, product development, primary target market introduction, and subsequent secondary market introduction, the authors distinguish between reverse innovation in the strong sense and reverse innovation in the weak sense. The five major flow types of each category of reverse innovation are discussed below.

Reverse Innovation in the Strong Sense

These innovations have at least two of its key innovation phases taking place in a developing country. The specific types are:

- *Developing country spillover*: Products conceived in advanced countries, developed and initially commercialized in developing countries, and then commercialized in advanced countries. An example would be that of the water purifier, Lifestraw, ideated in Denmark and developed in Vietnam for developing countries in Africa and Asia, and later sold in developed ones.
- *Double reverse innovation*: Products conceived in developing countries, developed in advanced countries, commercialized first in developing countries, and then commercialized in advanced countries. For example, Fiat 147, a flexible fuel vehicle, was originally conceived in Brazil and developed in Italy in the 1970s for the Brazilian market and later adopted in other developed markets.
- *Advanced country-targeted innovation*: Products conceived and developed in developing countries, commercialized first in advanced countries, and then commercialized in developing countries. For example, Research and Development for SAP's Business One Suite, an ERP system for small and medium-sized companies, is done by SAP Labs in China targeting customers in developed countries first before marketing it to its Chinese customers.
- *Developing country innovation*: Products conceived and developed in developing countries, and commercialized in advanced countries. For example, Bosch's R&D unit in Malaysia developed high-end screwdrivers that targeted Japan and subsequently European countries.
- *Reversed PLC*: Products conceived and developed in developing countries, and commercialized in advanced countries. For example, P&G created Vicks Honey Cough at its R&D center in Caracas, Venezuela, in 2003 with Mexico as its target market in mind, but 2 years later rebranded the product and marketed it to Hispanic customers in California and Texas, and to markets in Western Europe, the following year.

Reverse Innovation in the Weak Sense

These innovations have only one of its key innovation phases taking place in a developing country. The specific types are:

- *Spillback innovation*: Products conceived and developed in advanced countries and specifically targeting developing markets, but eventually commercialized also in advanced countries. For example, in 1990, Parmalat developed a new milk packaging ("milk in a pouch") in order to accommodate lower purchasing power in those countries. The same packaging was later introduced in developed countries like Canada as an environmentally friendly solution.
- *Cost/capacity innovation*: Products conceived in advanced countries, developed in developing countries, and commercialized in advanced

countries. For example, most of the core design in STMicroelectronics's TV set-up boxes is still done in France, but the main bulk of development is carried out in India, with their higher-end boxes targeting advanced countries.

- *Reverse spillover*: Products conceived in advanced countries, developed in developing countries, initially commercialized in advanced countries, and then commercialized in developing countries. For example, Siemens moved the development of its "*Advanced Multifunctional Operator Service System*" from Munich to Bangalore for cost and capacity reasons.
- *Front-end reverse innovation*: Products conceived in developing countries, but developed and commercialized in advanced countries. For example, Wuxi AppTech develops technological solutions that help global drug and medical device manufacturers shorten lead times and lower R&D cost, and targets customers mainly in the United States and Europe.
- *Developing country-inspired PLC*: Products conceived in developing countries, developed and commercialized in advanced countries, and then sold in developing countries. For example, Eli Lilly sold a cancer chemotherapy drug worldwide as Oncovin, first in the advanced world and later in Africa and other developing countries (Harris et al. 2015).

Caveats of Reverse Innovation

Even though reverse innovation shows tremendous promise, there are important pitfalls that companies must consider. Over the past few decades, some ventures have failed, while others have been converted to philanthropic programs. Only a limited number of them have gained commercial momentum. In order to be successful, such ventures should not be seen as a form of corporate imperialism focused primarily on profiting from the poor. They shouldn't either be a utopian quest for the impossible and a misallocation of investment capital.

The other major risk is for firms to avoid being seen as viewing the world's poor and rural spaces

primarily as laboratories for incubating innovations for the rich (Sarkar 2011). The poor should not be seen as guinea pigs for exploitation, but as underserved consumers with special and unique needs. The companies shouldn't be seen as being in the market just for cost constraints and looking for long-term higher returns in developed markets. Such circumstances are likely to damage long-term reputation of the firm and risk further operations in these markets.

In sum, reverse innovation is not a magic bullet. Companies should initially focus on serving the unique needs of the underserved in the bottom of the pyramid, and not think about how those innovations can be scaled up for the developed world. If they lend themselves to applications in the developed market by offering environmentally sustainable solutions to existing problems, then well and good, but that should not be the original goal for companies. Only the most sophisticated of the multinational corporations have been able to systematically benefit from reverse innovation. Understanding local needs, and the characterization of innovation flows across industries, they are advised to develop their own unique roadmaps leveraging their R&D capabilities and transforming themselves into being more competent global reverse innovators.

Summary

Reverse innovation is also known as trickle-up innovation and takes place when it initially takes place in a developing country before being introduced in a developed country. This is mostly taking place in industries such as banking, consumer products, energy, healthcare, technology, and transportation. Reverse innovation is typically considered to take place in four stages, including product ideation, product development, primary target market introduction, and subsequent secondary market introduction. These can take place in the strong as well as the weak sense. Even though the strategy has grown in popularity over the years, there are some caveats to which companies should pay close attention.

Rewards Effectiveness

Ewa Beck-Krala

Faculty of Management, AGH University of Science and Technology, Krakow, Poland

Synonyms

[Compensation effectiveness](#); [Remuneration effectiveness](#)

Definition

Rewards effectiveness may be defined as an effective rewards philosophy, procedures, programs, and tools used to reward employees for desired behaviors which, in turn, drive customer satisfaction and result in profits for the organization. Effective rewards are designed to be an extension of business strategy. Today, however, reward effectiveness may be widely defined in terms of meeting the objectives of the organizations, fulfilling the expectations of employees, or even realizing the needs of other organizational stakeholders, when viewed from the perspective of corporate social responsibility (CSR). Thus, it is a multidimensional construct which simultaneously combines the economic efficiency of the rewards, the level of achievement of the objectives of the system, and, additionally, *responsible rewarding*.

Introduction

Understanding rewards effectiveness and the scope of its evaluation process has evolved dramatically (Armstrong et al. 2011). Measuring rewards effectiveness is an important element of a strategic and integrated approach to rewards that help organizations achieve a sustainable, competitive advantage. To clearly understand the effectiveness of rewards, it is important to first define the most important terms. Traditional rewards programs were mostly financial in nature and emphasized the function of extrinsic motivation (Armstrong 2006; Bremen and Sejen 2012; Lawler 2000). Similarly, the traditional view on rewards effectiveness was mainly oriented toward economic efficiency (Corby et al. 2005) as well as on the achievement of the main goals of the rewards system (Gomez-Mejia and Balkin 1989). Additionally, the effectiveness of traditional rewards programs was highly discussed (see, e.g., Lawler 2000; Gerhart and Ryne 2003) because of high labor costs, without assuring employee commitment and loyalty function, one of today's most important goals.

A rewards system consists of the rewards policies and practices of a company. The main goals of this system are to attract, motivate, develop, and retain the best people in the workplace and to bring forward the best of their talents and passion (Smith 2013: 327). Moreover, the new trends in rewards, just as with sustainable rewards, enhance a strategic approach to rewards and integrate important goals, creating sustainable development for the organization's main stakeholders (Armstrong and Murlis 2007; Lawler 2000) and setting new directions in the evaluation process of rewards effectiveness (Brown 2008; Greene 2015; McMullen 2013; Scott et al. 2006). Today, the rewards effectiveness should be understood in a larger context. Previously, rewards were evaluated mainly from the perspective of economic efficiency. This involved analysis of expenditures relative to the achievement of the main goals of the rewards system, such as the ability to attract, engage, and keep the best employees. Today, however, this is not sufficient, and the new method of analysis will be explained in a broader meaning.

The New Approach to Rewards Effectiveness

Rewards effectiveness is generally understood in terms of the contribution of rewards programs to organizational strategy (Balkin and Gomez-Mejia 1990). Effective rewards programs help an organization gain a competitive advantage by attracting and retaining talented people and effectively impacting their attitudes and behaviors in the company. The term may be also widely defined in terms of meeting the objectives of the firm, fulfilling the expectations of employees, or even realizing the needs of other organizational stakeholders, when viewed from the perspective of corporate social responsibility (CSR) (Beck-Krala 2018). Effective rewards programs are designed to be an extension of business strategy (Ritcher 2002), explicitly supporting key priorities and goals and communicating the level and nature of the contribution the organization expects from its people (Bremen and Sejen

Rewards Effectiveness,

Fig. 1 The components of rewards effectiveness
(Source: Own based on: Scott and Beck-Krala (2019))

2012: 60). Thus, effective rewards within organizations foster integration of key stakeholder goals through effective rewards philosophy, procedures, programs, and tools used to reward employees for desired behaviors which, in turn, drive customer satisfaction and result in profits for the organization. The perspective of sustainable rewards in assessing the effectiveness of employee rewards requires calculating the return on investment for employee rewards while, at the same time, attending to the needs and well-being of key stakeholders of the organization (Beck-Krala 2018). It seems particularly important in light of reported cases of abuse related to unethical management practices, such as excessive employee stress and exploitation, wage discrimination (Transparency International UK 2016), or counterproductive employee behavior (Werbel and Balkin 2010) resulting from the ineffective or improper design of rewards programs. Rewards effectiveness is a multi-dimensional construct which simultaneously combines the economic efficiency of the rewards, the level of achievement of the

objectives of the system, and, additionally, *responsible rewarding* (Fig. 1).

Responsible rewarding, as a component of an effective rewards program, implies the need for sustainable human capital management and social analysis of the effects of applied rewards systems. This approach seems to be significant in the face of emerging abuse in this area and so-called consumption of human capital (Ehnert 2008), as well as emerging unethical employee behavior leading to high social costs (Klimkiewicz and Beck-Krala 2015). In this regard, effective rewards need to balance the interests of the main stakeholder groups and bring them value or at least do no harm in the short and long term. In practice, this means rewarding employees according to legal requirements as well as moral and ethical standards and evaluating the impact of the rewards on stakeholders. Thus, shaping sustainable rewards systems, apart from economic efficiency and effectiveness, focuses on creating a policy of equal opportunities and offering fair remuneration and a healthy and safe work environment which might be extended to work-life programs (Beck-

Rewards Effectiveness, Table 1 Main perspective of rewards effectiveness

Rewards effectiveness – main perspectives		
Supporting business strategy by realizing rewards strategy	Creating economic efficiency	Creating sustainable development and well-being of main organizational stakeholders
• Brings to the organization employees with required values, skills, and behaviors • Motivates and engages as well as keeps best employees	• Optimizes costs by internal and external financial analysis • Brings return on investments in rewards in a long- term perspective	• Is sustainable and socially responsible • Meets moral and ethical standards and norms • Brings value to all important stakeholders for the long-term • Does not harm the stakeholders

Source: Based on Scott and Beck-Krala (2019)

Krala et al. 2019). The cases of Volkswagen or Wells Fargo, where rewards programs unintentionally pushed employees to unethical behaviors that had negative impact on their customers (Transparency International UK 2016: 3), justify the need for such a broad understanding of rewards effectiveness. These three perspectives of effective rewards are specified in Table 1.

Evaluation of Rewards Effectiveness in the Literature Review

Sustainable rewards assume that regular monitoring and evaluation of effectiveness in achieving organizational goals and supporting employee well-being is an important part of this approach (Beck-Krala and Klimkiewicz 2016). Monitoring the effectiveness of rewards programs is important today, when many organizations face extensive competition for talent while working to optimize costs. Rewards systems become obsolete as a natural process related to the passage of time; therefore, systematic monitoring and evaluation of the effectiveness of rewards is necessary in the organization's management process. Despite the importance of the issue, little attention is devoted to this problem in both management sciences (Armstrong et al. 2011; Greene 2010) as well as in management practice (Brown 2014). Employers indicate the following reasons for failure to evaluate rewards systems:

- Lack of reliable measures (Corby et al. 2005; Brown 2008)

- Lack of conviction about the need for such analyses among managers and executives (Kearns 1995; Corby et al. 2005).
- Lack of resources, time, and specific information or data (Armstrong et al. 2011).
- Lack of knowledge and experience of the compensation professionals (Kearns 1995; Corby et al. 2005; Armstrong et al. 2011).

So far, most research on the evaluation of rewards effectiveness has been related to low awareness and the lack of such evaluation, for example, studies provided by Corby et al. 2005, Kearns 1995, and Armstrong et al. 2011.

Subsequent studies focused on potential criteria and measures used for rewards evaluation (Armstrong et al. 2011; Brown 2008; Scott et al. 2006; Corby et al. 2005). Only a small number of publications focused on a comprehensive approach to the evaluation process of rewards effectiveness (Scott et al. 2006; Brown 2008; Armstrong and Cummins 2011; Beck-Krala and Klimkiewicz 2016). Recently, developments in the literature related to effective sustainable rewards have been noted. This stream of research focuses on rewards in the context of CSR requirements underlying the cohesiveness of rewards with moral and ethical norms (Klimkiewicz and Beck-Krala 2017; Linder and Mottis 2013; Sahakiant et al. 2015), including the so-called Green Rewards (Renwick et al. 2012).

According to researchers, intuition and best practices are no longer enough, as rewards programs must be evaluated based on hard facts and quantitative measures (Gross and Friedman

2004). Incorporating the corporate social responsibility approach requires a more comprehensive methodology that includes both shareholder and stakeholder views (Beck-Krala 2018). Today, rewards systems must be regularly monitored and evaluated to achieve their goals. Depending on the characteristics of the organization and its needs, there can be various objectives of such evaluation, for example (Scott and McMullen 2014, Armstrong et al. 2011; Brown 2008; Scott et al. 2006; Corby et al. 2005):

- (a) Determining whether the rewards programs are well established
- (b) Verifying whether the programs meet their objectives as planned and support core human capital objectives and the objectives of the company
- (c) Verifying if the programs motivate employees to high performance and create employee engagement
- (d) Verifying if employees are satisfied with the programs
- (e) Diagnosing early potential problems with the programs and looking for further developments
- (f) Determining if the costs of the programs are optimized and affordable

Independent of the objectives, a systematic and comprehensive assessment of the rewards systems can be a source of many benefits for both the organization and its employees, for example, employee satisfaction and engagement, better performance, employee loyalty, and better work-life balance.

Evaluation of compensation systems is extremely important because direct and indirect rewards are often the largest expenditures made by a company. Without rigorous evaluation, it is difficult to determine if these resources are used well and, if not, how the rewards system can be improved. Despite the need to assess the effectiveness of rewards systems, few organizations evaluate their rewards systems or have any concrete evidence to justify their rewards practices (Armstrong et al. 2011; Beck-Krala and Scott 2013).

Comprehensive Approach to Reward Evaluation

In the literature, the comprehensive approach for rewards effectiveness evaluation can be found in the works of Scott et al. (2006), Armstrong et al. (2011), and Beck-Krala and Klimkiewicz (2016). As the last approach underlines the social perspective of evaluation, this model is presented in this publication. This model also incorporates the work of other researchers, e.g., the training efficiency model of Kirkpatrick and the return on investment measure (ROI) adapted by Philips (1996). However, the methodology concerns the rewards system and focuses on the most important aspects that should be evaluated. Moreover, rewards evaluation has adopted the CSR perspective and, therefore, requires a more comprehensive methodology that includes both shareholder and stakeholder views (Klimkiewicz and Beck-Krala 2015) (Fig. 2).

In this model, the authors proposed an analysis of the effectiveness of rewards systems from five dimensions (Beck-Krala and Klimkiewicz 2016):

- Philosophy of the system and its convergence with the firm's strategy
- Compliance of the system with formal regulations
- External competitiveness of the total compensation system
- Cost-effectiveness of the payroll (and return on investments from compensation)
- Satisfaction of the main stakeholders (e.g., employee satisfaction) with the system

Within these five dimensions, employers can analyze areas of the system that are most important to the organization. Based on the total rewards package (Armstrong and Cummins 2011) in a specific organization, the analysis should include these five perspectives. The components that should be evaluated include financial compensation, non-financial compensation, growth opportunities, and a safe and healthy working environment with hazard-free working conditions.

As employees are one of the most important stakeholders of the organization, their point of

Rewards Effectiveness, Fig. 2 Comprehensive model of reward effectiveness evaluation (Source: Based on Beck-Krala and Klimkiewicz (2016))

view may be taken into account when evaluating a rewards system. Therefore, widening the meaning and scope of rewards systems effectiveness will include such measures as employee opinions about the rewards system or customer satisfaction.

According to the research, rewards systems should be evaluated based on hard facts and quantitative measures. Managerial intuition regarding rewards programs and best practices are no longer sufficient (Gross and Friedman 2004). For many years, the effectiveness of rewards was reduced to economic issues based on the analysis of financial ratios and salary costs; therefore, quantity indicators and measures were mainly used (Armstrong et al. 2011; Beck-Krala 2018). For example, studies show that quantitative indicators related to job performance evaluation, e.g., improvement of productivity and quality of work, are most often used in industry (Beck-Krala 2018). Formerly, the focus on quantitative measures was most often characteristic of employers who considered rewards mainly in the context of the costs they generated and not the potential investments in employees and the benefits that the system could bring to the organization (Scott et al. 2006). Later, attention was paid to the goals and functions that

rewards need to meet, and rewards effectiveness was considered to be in the category of employee satisfaction with wages, so there was a focus on qualitative measures. Currently, when effectiveness of rewards must bring an added value to stakeholders, it is important to combine various perspectives and both qualitative and quantitative measures (Table 2).

The choice of adequate measures is not sufficient in and of itself. Another important issue concerns the whole **process of evaluation**. Scott proposed the procedure that explains main steps to be taken when analyzing and assessing rewards programs (Scott et al. 2006). The most important stages in the process are as follows:

- Setting goals or objectives of the evaluation
- Identifying evaluation criteria (according to the evaluation perspectives showed in the first dimension of the proposed model above)
- Selecting an evaluation methodology
- Collecting and analyzing data
- Interpreting findings
- Developing and implementing program improvement strategies

Rewards Effectiveness, Table 2 Measuring rewards effectiveness within an organization from the MSP sector

Dimension	Methods of evaluation	Measures/Indicators
The system is convergent (with business strategy and values)	Evaluation against organizational goals and success criteria	The firm has a clear and formal compensation strategy Alignment of business strategies or goals with rewards programs Goals are evident in incentives and performance assessment criteria Employees know and understand the compensation system
The system is compliant (legally, internally, fair)	Evaluation of equity and fairness of the system, compliance with legal regulations, and motivational rules	Analysis of average pay level for different demographic groups of employees at different positions Analysis of procedures and documentation on equal treatment and legal regulations Opinion of employees on equality in pay system and distribution of rewards Transparency of the system
The system is externally competitive	Evaluation of pay levels and attractiveness of the total rewards package against external market	Use of external survey Actual market position of the pay level Indicator of staff turnover Employee opinions on competitiveness of the total rewards (range of benefits, pay levels, incentive programs)
The system is cost effective and affordable	Evaluation and monitoring of payroll costs	Productivity indicators – the ratio of incomes compared with payroll costs monitored over time Average cost of employee compensation package compared over time and with the market Monitoring of HC ROI
The system satisfies employee needs and motivates employees	Are employees satisfied with the system? Are managers satisfied with the system? Are customers satisfied with the service provided?	Manager and employee opinions on the compensation system Cafeteria plan – flexible benefits Absence indicator The level of customer satisfaction Monitoring of customer complaints

Source: Based on Beck-Krala (2014)

Evaluation of perspectives, methods, and measures is important within the evaluation; however, this is just part of the evaluation process and not the end. The process itself, its continuity, and further action taken are important to receive desired outcomes and benefits of the evaluation process.

Summary

Understanding the importance of effective rewards indicates the need for regular monitoring and evaluation of the main dimensions of rewards effectiveness. The switch from the traditional to the new

approach toward rewards – such as sustainable rewards – has redefined the understanding of the term *rewards effectiveness*. Thus, today the term rewards effectiveness, apart from economic efficacy and goal achievement, also includes new aspects in the scope of analyses related to the social perspective and can be identified with the interests of the most important stakeholders of the organization, employees, and customers.

Rights of Employees

Alexandra Korcheva
Sofia University “St. Kliment Ohridski”, Sofia,
Bulgaria

Synonyms

Employee rights and freedoms; Employee rights;
Labor rights; Labor rights and freedoms

Definition/Description

Rights of employees is part of international labor law and covers all rights and obligations within the employer-employee relationship (Sepulveda et al. 2004). The narrower framework includes current employees, but a more intricate system of legal regulation can include former employees and job applicants into the category.

Rights of employees is part of the universal human rights, with them being stated in the Universal Declaration of Human Rights (articles 23 and 24) (UN 1948). On the international level employment law is governed by the system of international labor standards created and

administered by the International Labor Organization (ILO). The system of legally binding and non-legally binding acts creates a framework that acts as a unifying governance structure for countries, and near-universal worker protection (ILO 2019b).

The legal system of employee rights consists of universally applicable rights and sector-specific rights. Universal rights comprise of a few general categories: right to work (fundamental right that provides foundation to the whole legal system); right to privacy of the employee; right to due process; right to participation and association; right to occupational health and safety; right to fair wages (a category where both concrete issues such as minimum wage issues and overtime pay are considered, as well as more indirect problems such as gender pay gaps, etc.); freedom of speech and conscience; freedom from discrimination (UN 1948).

Sustainable organizations have the long-term goal to achieve balance between people, planet, and profit. Therefore, creating a working environment based on the protection of the rights of employees is therefore one of the essential features of sustainable management. This is part of the UN sustainable development paradigm (UN General Assembly 2015).

Employee Rights: The Old Way and the New Way

Perceptions about labor have evolved considerably in the last decades. Labor rights emerged as a natural human right, and were elevated by the national and international authorities. A significant role for the building and promotion of international labor law and standards was played by the International Labor Organisation (ILO) – one of the United Nations’ specialized agencies which focuses on fostering and enhancing the labor rights paradigm.

The classic way that labor has been perceived is the one of the worker not being the “bearer of power” (Painter and Puttick 2004, p. 7). Leading labor law expert Kahn-Freund provided an

influential perspective of the employment relationship was that of the power structure in which the employer held the decision-making power and the worker is subordinated to the employer (Davis and Freedland 1983; Painter and Puttick 2004). On the basis of his analysis Kahn-Freund provided the perspective that labor law holds the main function to provide a force that can counteract to the employer-employee inequality in bargaining power. The most well-known labor market models in neo-classical economics support this view of labor relations.

However, a new ideological understanding has been evolving in recent years. The so-called New Labour transformation it has argued that an emphasis on promoting equality of opportunity and capabilities has become an integral part of labor relations, and a system in which workers are able to participate in the benefits of a stronger labor market, and a more prosperous and competitive economy is in order (Painter and Puttick 2004, p. 7).

The transformation of labor relations has brought changes in both the perceptions of stakeholders, and the management framework of companies. More and more companies have realized the benefits of higher employee engagement into the company, such as being shareholders, or being regarded as partners rather than subordinates. In this new paradigm, labor rights gain a new type of significance – that of a framework for cooperation between partners, rather than an instrument for equalizing bargaining power.

Employee Rights Between Two Contexts

In recent years there has been a debate between scholars whether labor rights and their protection could be appointed to the sustainable development paradigm as part of the social sustainability side of the concept.

Applying labor rights to the framework of sustainable development seems appealing to both scholars and practitioners. However, the existing international instruments, including the United Nations (UN) Sustainable Development Goals

(SDGs), do not provide enough clarity on the relationship between the environmental, economic, and social aspects of a sustainable development agenda, as well as their application in practice (Novitz 2020).

The sustainable development framework, however, has been considered as a more likely alternative for the development of labor rights regimes, as business is more willing to cooperate within this framework, as it adheres to economic efficiency more than the traditional employee rights paradigm of the ILO (Novitz 2020).

Key international settlements such as the UN Resolution on Agenda 2030 for Sustainable Development (UN General Assembly 2015) and the UN SDGs thus gain a pivotal role for the future development of labor law and regulations. Some even argue that sustainability can be perceived as a “double agent” for promotion of employee rights and support to worker claims (Matthysen 2020).

Employee Rights at a Glance

Right to Work

The right to work is the fundamental human right that stands in the center of employment law. Established in the Universal Declaration of Human Rights, it has become a core principle in the legal framework of labor relations.

According to the UN Committee on Economic, Social, and Cultural Rights (CESCR) the right to work has the following features:

- Availability – states should help workers seek employment opportunities and find work.
- Accessibility – access to work is achieved through ensuring physical accessibility, information accessibility, and non-discrimination.
- Acceptability and quality – people should be ensured the right to choose work freely, with every employer providing at least the minimum safe working conditions provided by national and international labor standards (CESCR 2006).

Right to Privacy

Employee privacy rights are the rules that aim to limit the employer's interference into the employee's personal life and possessions. They set the limit on how an employer can monitor the employee's actions or communication with others. The right to privacy protects employees on the extent to which an employer has the right to acquire information about the personal life of the employee both in the workplace and outside of it. Employee right of privacy has been a trend of rising importance with the advent of social media and online presence of people.

Right to Due Process

Due process refers to fairness in procedures and legal matters, with the rights of the parties involved protected and the process kept free from discrimination and prejudice (UN 2003, p. 251). Due process is applicable to any formal proceeding and constitutes the necessity to apply the established rules with fairness. In the employer-employee relations due process is most commonly regarded in relation to lawful termination. Even in most severe matters of termination of the work relation, employees still have rights that have to be protected. It is not unusual for employees to contest a termination or other types of punishment forms in court.

Right to Participation and Association

The right to participation and association is the foundation of labor union and professional associations of workers. It is the right of workers to organize and take collective action in protecting their rights and interests. As it is considered that the employer has a natural supremacy in power over the employee, the right to participation and association provides employees with the possibility to overcome this natural power asymmetry. The right to participation and association allows the employees to take part in unions and forbids employers to let employees go on the basis of union participation. Employee associations have the ability to perform collective negotiations authority, with the purpose to protect employee rights and negotiate better conditions with the employers (Burda and Wyplosz 2008).

The right to participation and association has been secured by a number of international legal acts, including the fundamental:

- Universal Declaration of Human Rights (UN 1948)
- International Covenant on Economic, Social and Cultural Rights (UN General Assembly 1966)
- Freedom of Association and Protection of the Right to Organise Convention (No. 87) (ILO 1948)
- Right to Organise and Collective Bargaining Convention (No. 98) (ILO 1949)

Different analysis of worker rights conditions in this field have been performed as part of social and economic analysis of the labor market. One measure of civil liberties and workplace-oriented measure of freedom of association and collective bargaining rights (the FACB index) shows stronger labor rights in open economies (Flanagan 2006, p. 29).

Right to Healthy and Safe Working Conditions

Occupational health and safety refers to the right of workers to perform their jobs in maximally safe environment that does not cause deterioration in their physical or psychological health (Joint Industrial Safety Council 1987). Occupational health and safety standards are widely promoted by the International Labor Organization, and are usually well regulated by national legislations. Some sectors of economic activity, however, always bear some occupational hazard due to the nature of the production process, for which reason special legislation and specific international standards are adopted.

Right to Fair Wages

The right to fair wages is provided by both the Universal Declaration of Human Rights and the International Covenant on Economic, Social and Cultural Rights (UN 1948; UN General Assembly 1966).

The international labor standards set by the International Labor Organization (ILO) cover the

topic of wages among others (ILO 2019a, b). Relevant ILO instruments are the Protection of Wages Convention (1949), the Equal Remuneration Convention (1951), the Minimum Wage Fixing Convention (1970), etc. (ILO 2019a). The right to fair wages has been considered to cover the topics of minimal pay, as well as wage inequality in the workplace and gender pay gaps in the workplace.

Freedom of Conscience and Speech

The freedom of conscience and speech in employment law refers to the impact that personal opinions on social, religious, and political topics could have on employer-employee relations. It guarantees the right of employees to express their personal opinions on different topics freely. The topic is one where delicate balance is sought after, as employers sometimes do have the right to sanction employees should their expression become abusive, implies discrimination, or is a demonstration of a socially unacceptable behavior (United Nations 2003, p. 525).

Freedom from Discrimination

The freedom from discrimination principle implies that the amount of employees' pay should not depend on sex, race, or any other discriminative factor. The freedom from discrimination is perceived to be one of particular importance in women's rights regarding labor.

Economic theory too predicts that increased competition between companies to hire labor leads to erosion in discrimination, with employers with less discriminatory tastes having a larger pool of labor force they can choose from (Flanagan 2006, p. 63).

Summary

Protecting employee rights is an essential part of the functioning of any business, and it is considered to be a core prerequisite for sustainable management of companies. With employee rights protection being a well-developed system of legal acts on both international and national

levels, convergence of companies from around the world toward a common culture of sustainable worker-employee relationship is promoted. While disputes in this relation still show that problems of power asymmetry are still present in the worker-employee relations (globally, there are regions in the world where severe problems stand unresolved), it is clear that the overall trend of development is toward achieving sustainability in this field.

Definition/Description

The Rio Declaration on Environment and Development is one of the two main political documents adopted at the United Nations Conference on Environment and Development, held in Rio de Janeiro between June 3 and 14, 1992, also known as the Earth Summit (United Nations 2023a).

The declaration consists of 27 principles, which outline the rights and responsibilities of countries to achieve sustainable development. The Declaration addresses international and domestic issues, and it specifically outlines the international nature of most environmental problems. It proclaims the necessity for responsible action of nation states on both the national and international level, to solve such problems (United Nations General Assembly 1992).

The Rio Declaration is a document of considerable political significance, as it is a written

expression of the fundamental ideas that formulate the ideological basis for future policy and decision making and balance between socioeconomic development and the environment.

From the standpoint of international law, the Declaration is not a legally binding document, unlike traditional sources of international law, such as treaties and conventions. However, as it expresses fundamental principles of social affairs and interactions, it is considered by some experts a supplementary source of international law, much like customary law and international principles (Popovic 1993).

The principles that are drawn in the Rio Declaration are fundamental in the sphere of environmental law. They are often considered the formal expression of the fundamental values that are drivers for the change towards a more environmentally sustainable way of using natural resources.

How Did the Rio Declaration Come to Be?

The effort towards sustainability was commenced at the 1972 United Nations Conference on the Environment, held in Stockholm, Sweden. The event was the first world conference to center the environment as the main issue that nations should address. The main outcome of the conference was the adoption of a series of principles for sound management of the environment including the Stockholm Declaration and Action Plan for the Human Environment (United Nations 2023b).

The Stockholm Declaration of 1972 contained 26 principles, and it placed environmental issues at the center of international concerns. This political document marks the start of a dialogue between industrialized and developing countries on the link between economic growth, air, water, and ocean pollution (United Nations 2023b).

The second global conference that focused on environment and development was the United Nations Conference on Environment and Development (UNCED), also known as the “Earth Summit,” held in Rio de Janeiro, Brazil, from June 3 to 14, 1992. The conference took place

on the occasion of the 20th anniversary of the Stockholm conference of 1972. It brought together political leaders, diplomats, scientists, media, and nongovernmental organizations from more than 179 countries (United Nations 2023a). The main objective of the Earth Summit was to produce an agenda and a new plan for international action on environmental and development issues that would help guide international cooperation and development policy in the future. Thus, the Rio Declaration on Environment and Development was created, being one of the main political documents signed at the Earth Summit. The package of documents included other seminal legal and political documents such as the United Nations Framework Convention on Climate Change (UNFCCC), the Convention on Biological Diversity, the Declaration on the principles of forest management, and Agenda 21 (United Nations 2023a).

The history of the negotiation process of the Rio Declaration shows the long-standing divergence in opinions between developed and developing countries in terms of environmental governance. Evidence shows that developed countries and NGOs wanted the Earth Summit to conclude with an “Earth Charter,” which would focus on environmental issues (Louka 2006, p. 33). For that reason, the proposal of such a charter was rejected by the G-77 and China as they reviewed it as a measure that would be accepted at the expense of the economic development of developing countries and emerging economies (Louka 2006, p. 33). For this reason, the Rio Declaration did not assume a purely environmental focus and instead is heavily influenced by the ideas of fair and equitable economic and social development of states.

The 1992 Rio Earth Summit was followed by a number of conferences in the coming decades. The most prominent of those were the 2002 World Summit on Sustainable Development, or Rio+10, held in Johannesburg (South Africa), and the 2012 United Nations Conference on Sustainable Development (UNCSD) or Rio+20, held once again in Rio de Janeiro (Brazil).

One of the main political outcomes of the 2002 World Summit on Sustainable Development was

the Johannesburg Declaration, which built up on the principles of the Rio Declaration and provided an even stronger focus on social and economic development of states.

Another powerful tool for international cooperation after the signing of the UNFCCC became the Conferences of parties (COP) meetings of member states to the convention. With the adoption of the Kyoto Protocol, and in 2015 – of the Paris Agreement (United Nations Climate Change 2023), COP meetings became the most prominent global political forum for climate change discussions and advancement.

Implementation of the Rio Declaration

The main philosophy of the Declaration is that human development and environmental protection should evolve together, and it is best that they are not considered separately. This understanding has come to dominate the sustainability paradigm on a global level and in terms of theory, and it is one of the cornerstones of practical decision-making.

Central principles relating to development in the Declaration that find significant development in international politics after the adoption of the document are the principle of centrality of human beings to the concerns of sustainable development (No. 1); the primacy of poverty eradication (No. 5); the importance of the environment for current and future generations and its equal footing with development (No. 3 and 4); the special consideration given to developing countries (No. 6); the principle of common but differentiated responsibilities – CBDR (No. 7) (Stakeholder Forum for Sustainable Future 2011). These principles are also acknowledged and enriched in the Johannesburg Declaration of 2002. The principles regarding economic and social development also constitute the foundation of the United Nations Millennium Development Goals and the Sustainable Development Goals that inherited and enriched the movement later. Their practical application has also been found within the conduct of UN specialized agencies such as the UNEP, UNDP, UNICEF.

The Declaration also enshrined the two critical economic principles of polluter pays (No. 16) and precautionary approach (No. 15), and it introduced principles relating to the participation and the importance of specific groups for sustainable development (No. 10, 20, 21, 22) (Stakeholder Forum for Sustainable Future 2011).

The Rio Declaration also included the duty of notification in emergency situations or when a country is to engage in an activity likely to have transboundary environmental impacts – a rule that would later on become an important part of the principles of international environmental law and would be featured in different international legal tools (Louka 2006, p. 141).

From an empirical standpoint, the principles of the Rio Declaration are a soft law instrument, and their implementation may take many shapes (Stakeholder Forum for Sustainable Future 2012). While quantifying the number of acts that stem from the Declaration is a significant challenge, there are various international agreements or national acts that have transposed the Principles. Where principles have been applied in practice, their application has often been tested in courts. In the case of international law, the result is that some of the Rio Declaration principles have been accepted as part of international jurisprudence (Stakeholder Forum for Sustainable Future 2012).

The most prominent examples of the legal application of the Rio Declaration's Principles are within the application of Principles No. 5, 10, 15, 17, and 24, all of which demonstrate varying elements of successful transposition and wide adoption of the principle in legal acts. Studies show that principles No. 3 and 21 are also steadily gaining momentum on implementation and that increasingly more effort is being made to apply them in practice (Stakeholder Forum for Sustainable Future 2012).

In international law, the principles of the Rio Declaration are reviewed as a supplementary source of law. Much like customary law, their legal significance is confirmed in international case law. Two examples of using the Rio Declaration principles in judicial decision-making on the international level are the invoking of

Principle No. 2 in a few cases in international courts and the invoking of Principle No. 17 in cases such as *Pulp Mills on the River Uruguay* (Argentina v. Uruguay) (Stakeholder Forum for Sustainable Future 2011).

Poverty Eradication and the Contribution of the Rio Declaration

On a local level, the declaration's principles focus on the need of each state to achieve endogenous economic growth while protecting the environment and minimizing the negative environmental externalities that economic activity creates. The declaration puts a stress on the need to engage women and youth in the process of achieving sustainable development.

The Rio Declaration stresses the necessity to achieve a balance between developed and developing nations. By acknowledging the historical role of developed states in man-made climate change, and the need for those countries to bear the relative bigger cost of current pollution eradication, it confirms the right of developing countries to achieve economic growth and stresses the importance for global poverty to be addressed by both developed and developing countries in a joint effort to eradicate it.

The first principles of the Rio Declaration have become a significant instrument of the strive of the United Nations towards promoting the economic growth of developing countries. Consequently, high-level forums and the work of UN agencies on development put a strong emphasis on the creation of a socially equitable society in all countries.

A direct successor of Principle 5 (eradicating poverty and raising the standards of living for all) are the Millennium Development Goals (MDGs) and the Sustainable Development Goals (SDGs) at a later stage (Stakeholder Forum for Sustainable Future 2012). With the system of the SDGs being the most comprehensive so far, with them being adopted across national economies as key performance indicators (United Nations General Assembly 2017), the first and second Rio Principles have become

one of the most highly institutionalized goals of the member states.

Rio Declaration and the Participation of Citizens in Sustainable Development

The Rio Declaration is also a document that aims to promote citizen's participation in environmental decision making. The delegates at the United Nations Conference on Environment and Development of 1992 agreed upon that environmental issues can be best handled with the participation of all concerned citizens at the appropriate level of governance (Popovic 1993).

In terms of national governance, the delegates agreed that good governance is a significant part of the mechanisms for sustainable development. They reassured that the right to access to information concerning the environment and the opportunity to participate in decision-making processes, as well as the provision of effective legislative, executive, and judiciary services by the state to its citizens were outlined as primary rights of citizens that should be guaranteed (Popovic 1993).

As a result, the Rio Declaration became one of the instruments that increase the participation of citizens in the public governance process, safeguarding the opportunity to create binding obligations on states regarding participation of the public in environmental decision making (Popovic 1993).

Principle 10 is the foundation of the UNECE Convention on Access to Information, Public Participation in Decision-making, and Access to Justice in Environmental Matters (Aarhus Convention). The Aarhus Convention has provided valuable means by which the various elements of the Principle have been promoted through application at the national level, as well as providing a forum (the Compliance Committee) that can hear complaints where it is claimed that Nation States are not adhering to the Convention (Stakeholder Forum for Sustainable Future 2012).

Notably, cases have been brought by civil society organizations that have challenged their government's lack of implementation or compliance to the Convention, which has resulted in the

development of a body of caselaw that has strengthened the principle overall. Since the adoption of the Aarhus Convention by the European Union, there has been a booming of cases in front of the Court of Justice in the EU (Andrusevych and Kern 2016).

The Precautionary Principle, the Polluter Pays Principle (PPP), and the Environmental Assessment Principle

Principle 15 is also known as the Precautionary Principle. It introduces the understanding that environmental protection should be promoted wherever there are “threats of serious or irreversible damage, and that lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation” (United Nations General Assembly 1992).

This principle has been widely accepted as a foundation of environmental law at both the national and international levels. It has been tested in a range of courts and jurisdictions, notably the World Trade Organisation (WTO) arbitral body where initially it was found in some cases that trade rules superseded the precautionary principle.

Despite the development of this principle in both theory and practice, there have been many concerns that it can be used as a trade barrier by different states and could also create a bias against new technologies and processes (Louka 2006, p. 34).

The application of the precautionary principle is also highly dependent on the states’ politics. For example, the United States, having a skeptical approach towards the principle, views it as a new nontariff barrier to trade. On the opposite side, the European Union has transformed the principle into a constitutional principle and applies it largely to its trade policies (Louka 2006, p. 51).

Principle 16 is widely known as the Polluter Pays Principle (PPP). It states that polluters should bear the costs for their pollution and that countries have the rights to exploit their own resources sovereignly only if they do not endanger

the environment of other countries (United Nations General Assembly 1992). The PPP principle establishes a demand for the person who is in charge of polluting activities to be financially responsible for the damage caused by pollution (Louka 2006).

Over the years, the PPP has gained significant influence in both environmental law and environmental economics. In both international and domestic law, this principle has found itself to be a seminal rule of thumb (e.g., the philosophy behind greenhouse gas emission quotas). In economics, the PPP is most often regarded within the scope of the Coase vs. Pigou approach towards environmental harm and sanctions (Baffi 2012). It is an opinion expressed by scholars and practitioners that the principle’s practical value is diminished because most polluters will tend to pass the costs of pollution onto consumers (Louka 2006). Thus, the principle also raises the question of the price of the final good and whether allocation of a pollution sanction to the polluter may lead to a rise in prices that would ultimately cause society to be worse off instead of better off (Bugge 2009).

Despite its relevant simplicity in wording, the PPP may also have much more complex economic and institutional implications due to the nature of the polluting activities that it regulates. It is very often not a single entity that causes the pollution, and it becomes harder to allocate the polluter sanction as a longer production chain is involved (Bugge 2009). Thus, the application of the PPP may lead to social justice dilemmas (Bugge 2009).

Despite the critique it has faced, the PPP has put a foot in the right direction in relation to the more careful consideration of effectiveness of economic and institutional approaches towards environmental regulations. While it cannot be expected for a single universal principle to succeed in reducing all negative consequences, effectiveness is more easily achievable through an efficient combination of social, political, economic, and biophysical considerations (Swaney 1992). In this sense, the PPP principle provides a significant political step forward in the consideration of environmental impact and accountability.

Principle 17 concerns Environmental Impact Assessments (EIAs). Principle 17, alongside Article 14 of the Convention of Biological Diversity, and specific provision of Agenda 21, became the foundation of the political effort to make states introduce EIAs into their national legislation (Sánchez and Croal 2012).

EIAs have a significant development in the face of the adoption of these rules by a number of countries and also by international financial institutions such as the World Bank, the International Finance Corporation, and others that also acknowledged this practice. In 2003 the Equator Principles were launched by commercial banks as voluntary commitments to incorporate the results of environmental and social assessments into certain credit programs (Sánchez and Croal 2012).

The development of EIAs into strategic environmental assessments (SEA) has been highly supported by the European union (EU) and the Organization for Economic Cooperation and Development (OECD) (Sánchez and Croal 2012).

Challenges to the Principles of the Rio Declaration

Upon its negotiation and adoption, some experts have claimed that the outcome of the Rio Declaration presents a step back from the Stockholm Declaration (Louka 2006, p. 35). There has been difficulty in applying the Rio Principles in practice.

In terms of eradicating poverty, despite the Rio Declaration provides a political foundation for the MDGs and that they have had a significant impact on the reduction of poverty on a global level, nations still face difficulties in reducing disparities in standards of living by lowering both national and across-country inequalities (Stakeholder Forum for Sustainable Future 2011). This aspect is now addressed by the SDGs in the hope that this agreement set out in Rio will lead to a successful resolution.

In terms of civil participation in environmental decision making, despite Principle No.10 has achieved success with being recognized and implemented in legal acts, there is still lack of

ability for many groups and stakeholders to participate in the process at national and local level (Stakeholder Forum for Sustainable Future 2012).

The precautionary principle, while successfully implemented in a range of instruments and tested in case-law, remains mired by ideological divergence, and in relation to the PPP, there remain some ideological and economic differences to its practical application which have undermined the successful implementation of the principle on the whole.

In terms of achieving sustainable production and consumption (No. 8), there has been a setback in achieving this principle. Despite the impressive national and international efforts, global production is still a long way from the sustainability levels that are ever more required, and in terms of global consumption, there are still global patterns of consumption that are unsustainable but that have been left largely unaddressed (Stakeholder Forum for Sustainable Future 2011).

There are also local tensions in terms of the application of national sovereignty on resources of Principle No.2. On a transnational and global level, there are still too many issues associated with management of the commons that relates to trans-boundary pollution, climate change, and biodiversity (Stakeholder Forum for Sustainable Future 2011). Nations have still not found the best institutions that would create sustainable management of common pool resources that are spread out between many people on a large territory, thus creating conditions for transboundary prisoner dilemmas, and potentially “tragedies of the common” (Hardin 1968).

Summary

The Rio Declaration gives people the right for development but also the obligation for preserving the environment. It highlights the need for effective public-private cooperation, as the nature of the environment as a common good dictates such a cooperation. The declaration emphasizes that humans are in the center of the sustainable development, but it stresses that human activity should not harm the environment in such a way

that future generations will bear the negative externalities in time.

Despite some setbacks in application, the Rio Declaration and the Rio Principles are a major political commitment towards sustainable development and have become a significant part of the international environmental legal framework.

Definition

Risk management (RM) is a process of identifying, evaluating, and prioritizing risks, followed by response actions and monitoring. Risk differs from uncertainty, because probabilities may be calculated for risks, but not for uncertainty, which refers to more fundamental unknowns. The RM goal is usually not to eliminate all risks, since this is typically either impossible or very costly. The point is managing risks at an acceptable level ensuring the best balance between threats and opportunities, in particular critical risks and those that are more likely to materialize. While everyone needs to manage risk, even if our job is not being a risk manager, taking risk is fundamental in business.

RM is an ongoing and iterative process, which must be repeated indefinitely, not only because risks cannot be fully and definitely eliminated but also because risks are permanently changing. The social, political, and business environment is constantly changing, and new threats, vulnerabilities, and opportunities emerge every day. Individuals, governments, or organizational risk managers should also understand and consider the velocity of risk. While new risks continue to

emerge at a fast pace, particularly given an increasingly hyper-connected business environment, digital transformation is promoting more effective, predictive, and continuous organizational RM tools, through continuous gathering, comparison, and correlation of data, hence helping to reduce those risks or their undesired consequences.

Introduction

All organizations and individuals face threats, internal or external, that may significantly affect their activities and sustainable value. The starting point of RM is the definition of risk. Risk should be something that can be quantified, even if not very precisely. Risk is measured taking into account the probability of something occurring, together with the related potential impact. However, no probability may be assigned to uncertainty, thus rendering the management of uncertainty extremely difficult. RM deals with foreseeable risk events with determined potential outcomes – and while the notion of risk is typically associated with negative outcomes, positive outcomes should also be considered. Risks are selected for attention and treated on an ongoing basis to diminish the associated likelihood of occurrence and/or the consequences of events affecting objectives. The growth of RM is linked to the growth of risks themselves, due to a more globalized and complex world, to the increasing availability of technological tools to support effective RM, and to regulators and investors calling for greater disclosure of RM policies in order to better understand financial and nonfinancial risks faced by organizations.

An increasingly important area of risks for businesses derives from an increasing emphasis on social and environmental sustainability, rather than just financial and economic sustainability [1]. The World Economic Forum commented, in its 2019 Global Risks Report, that “Environment related risks account for three of the top five risks by likelihood and four by impact” (World Economic Forum 2019, p. 15). Investors are increasingly paying attention to environmental,

social, and governance (ESG) [2] risks when making investment decisions, and organizations are being held accountable for the impact of their activities. As an example of this increasing attention, Principles for Responsible Investment (PRI) [3] were developed by major investors and supported by the United Nations. UNPRI (2019, p. 4) defines “responsible investment as a strategy and practice to incorporate ESG factors in investment decisions and active ownership,” in order to promote long-term, sustainable value. Clearly, as sustainable investment has been shifting from a niche to a more mainstream approach, managing sustainability and ESG risks has therefore become more prominent and more deeply integrated into and alongside the wider organizational strategy.

Given the increasing, and necessary, inclusion of sustainability within wider managerial concerns and processes, this text aims primarily to provide an overview on RM in general, to assist an effective inclusion and management of specific sustainability risks, alongside the other general risks.

Risk Management Frameworks

The scope of RM may be narrower (such as credit, operation, reputational, financial, or IT RM) or wider (enterprise-wide RM – ERM). Several frameworks provide principles and generic guidelines on RM that can be used by any public or private organizations and even individuals. Examples include the Australia/New Zealand Standard for Risk Management (AS/NZS ISO 3100:2009 “Risk Management – Principles and Guidelines”); the International Organization for Standardization standard (ISO 31000:2018); the International Electrotechnical Commission standard (IEC 31010:2019 “Risk management – Risk assessment techniques”), which complements ISO 31000:2018; and the Committee of Sponsoring Organizations of the Treadway Commission (COSO) framework. The “Enterprise Risk Management – Integrated Framework,” published by COSO in 2004 (COSO ERM), has been widely accepted and used by organizations in their approach to manage corporate risks in an

integrated way. In 2004, COSO defined ERM as: “...a *process*, effected by an entity’s board of directors, management and other personnel, applied in strategy setting and *across the enterprise*, designed to identify *potential* events that may affect the entity, and *manage* risk to be *within its risk appetite*, to provide reasonable assurance regarding the *achievement of the entity objectives*” (italics added to highlight major topics of an ERM). An updated framework, titled “Enterprise Risk Management – Integrating with Strategy and Performance,” published in 2017, shed light on the importance of embedding risk both into the strategy-setting process and in driving performance, as risk influences and aligns strategy and performance across all departments and functions (COSO 2017). COSO ERM is used for identifying risks, managing those entity-wide risks within a defined risk appetite defined by management and supporting the achievement of the strategic objectives of the organization (COSO 2017).

Globally, the described RM frameworks for managing risk have far more similarities than differences, and they all describe a process for embedding RM into the organization’s governance, strategy and planning, management, values, and a strong corporate culture about risk.

Risk Threshold Development

The RM goal is to assess and proactively prevent risks from reaching dangerous levels, keeping them within acceptable predefined thresholds. These limits are called risk appetites. Risk appetite is an integral part of ERM (COSO 2009) and represents the balance between potential benefits and dangers of taking certain actions. Therefore, the starting point before conducting any RM activities is the definition of the overall risk appetite and the acceptable tolerance per risk category.

Alternative strategies need to be articulated with risk thresholds. Consequently, risk appetite levels need to be set in adherence with the overall risk culture of the organization and its strategic objectives. Once the risk appetite is defined, it needs to be embedded and continuously enforced across the organization to ensure a broadly

common risk language, monitored over time and revised in light of a changing competitive environment or strategy. Risk tolerance is related to risk appetite and objectives. While risk appetite is broad, risk tolerance is operational, defining the actual boundaries for the various risks (COSO 2009). However, defining which risks or levels of risk should be accepted or avoided is challenging, due to increasing uncertainty around regulatory, political, social, and market environments.

Risk Management Process

The RM process begins with the identification and quantification of risks, which implies developing risk scenarios, quantifying impact, and assessing probabilities through RM tools. Based on risk thresholds (risk appetite and tolerances) defined by management, risks are prioritized and mitigating actions taken to address critical risks in terms of likelihood and impact. Identifying and assessing the strength of interconnections between risks, as well as between risks and potential mitigating actions, is fundamental to define priorities and to avoid, or at least manage, contaminations.

In today's fast-paced digital environment, actions taken to address risks should be preventive as much as possible, and not only reactive, as risk event outcomes emerge with disarming velocity. RM needs to focus on risk likelihood, impact, and velocity (how quickly the risk would generate an outcome), and not only on the first two variables (Ernst & Young 2018).

Risk Monitoring

Key risk indicators (KRIs) are used to indicate changes in risk or to provide early warning signals. Defining proper qualitative and quantitative KRIs, alongside the more traditional key performance indicators (KPIs), may be challenging. However, defining KRIs is fundamental to embed RM in everyday management concerns, rather than remaining a separate activity, since managerial behavior has been shown to be

influenced by measurement processes, particularly when tied with incentives. Risk appetite levels and risk tolerance need to be reflected in each KRI to try to keep activities within the overall desired risk appetite defined by management. Reported KRIs, alongside traditional KPIs, should be monitored on an ongoing basis and actioned upon in a timely manner when further mitigation is required.

Measurement of sustainability data is not simple, so defining KRIs and KPIs incorporating environmental and social dimensions has been challenging. Various providers of sustainability indicators and information have emerged, although differences in calculation methodologies and issues around data exist. As one example of such sets of indicators, the Sustainability Accounting Standards Board (SASB) has developed a Materiality Map[®] that identifies sustainability factors likely to impact the financial condition or operating performance of organizations within a given industry, providing very specific accounting metrics.

Akin to the challenge of choosing among a wide diversity of indicators is the challenge of deciding risk mitigation actions. In fact, due to the high interconnection and complexity of the current business context, adverse, even potentially unintended, impacts from risk mitigation actions may emerge. So, organizations taking actions which improve scores in particular indicators may face themselves with deteriorating performance according to other indicators.

Communicating and Reporting Risk

RM practices should not be limited to ad hoc discussions between management and risk managers. Formal risk maps and risk scorecards conveying risk likelihood, consequences, and any interactions and dependencies between them, as well as the actions for mitigation of critical risks, should be communicated both within the organization and between organizations and their environment. It is also important to preserve the insights regarding key risks when undertaking

their identification and assessment, in order to support further review and update processes.

Formal and clear roles and responsibilities should be defined for any risk function, in particular, risk appetite setting, approval, and review, as well as risk owners that have the primary responsibility for managing risk. Such roles and responsibilities must be duly communicated within the organization. In organizations with mature RM functions, reporting may be done to a Chief Risk Officer or a Chief Information Risk Officer, rather than directly to the Chief Executive Officer; however, the most important thing is having a clearly defined reporting line for KRIs.

Dissimilarity of Risk Management Practices

RM frameworks do not imply uniformity of RM techniques across organizations. RM activities need to be customized to meet every organization's goals and objectives, taking into account its structure, processes, operations, projects, or products. Managing the risk of each organization depends on its risk profiles, tolerance and appetite for risks, and the extent to which day-to-day business decisions comply with that threshold. As each organization has different missions and strategic objectives, different risk appetites will be established (COSO 2009). There is no "right" risk appetite and tolerance and no one-size-fits-all standard.

Managing External and Uncontrollable Risks

Complexity and interconnectedness have increased the incidence of "black swan events," extremely rare risks, unknowable and unpredictable before they occur, for example, the 2007 financial crisis or the 11 September terrorist attack. Significant losses may be incurred from ignoring and not managing effectively such external and uncontrollable events (Taleb et al. 2009). Kaplan and Mikes (2012) suggest that organizations should qualitatively distinguish preventable,

strategic, and external risks in their approach to effective RM processes. Preventable risks are internal controllable risks arising in routine operational processes, due to internal problems related with, for example, budgeting, human resources, or project management; these preventable risks should be avoided through mechanisms like automation or treated through rules and internal control monitoring. Strategic risks are incurred when seeking to increase performance to maximize value and depend on strategic objectives. Managing these risks requires open risk discussions and cost-benefit analyses for reducing the likelihood of unfavorable risk events or mitigating related outcomes. Finally, an alternative approach is required for external risks, which are non-preventable risks that arise externally to strategy and operations and are beyond the influence and control of the organization, such as political, geopolitical, and environmental changes and natural disasters. As typically unlikely and unpredictable risks, RM should focus on their potential impact and on how to best mitigate their effects should they occur (Kaplan and Mikes 2012).

Technological Developments for Risk Management

Building agile and flexible RM tools and techniques is key to respond quickly to current market dynamics. Technological advances allow for closer and more realistic measurement of risk, using algorithms and probability models for risk evaluations and monitoring on a real-time basis. More risk data being monitored by complex and statistical systems enables to identify and focus on high-priority risks. Rethinking how risks can be identified, assessed, and monitored by means of emerging technologies, such as robotic process automation (RPA), big data, the cloud, and artificial intelligence (AI), will also change the way risk is being managed. RPA, by automating repetitive tasks, will free up risk managers for more strategic added-value work. The emergence of big data, diversified types of data characterized by high volume, velocity, and variability, largely increased the potential to identify and monitor

multiple risks near real time, potentially using cloud solutions to access the large resources (from storage to computing power) required to explore that data. This exploration will be driven by AI, which will enable predictive analytics and insights by modeling future scenarios for testing risk hypotheses, drawing upon the increasingly large amounts of information available.

However, digital initiatives in a world of more and more data and more automation also require managing the risks of sophisticated cyberattacks, putting security and confidentiality at stake. Over recent years, cyber-risks have increased in terms of impact and likelihood, leading to theft of data and negative impact on operations (World Economic Forum 2019). Risks like biases in AI also expand the list of risks to be managed. Another challenge raised by big data to RM is information overload. With the proliferation of data, RM needs to adapt (COSO 2017), and automated monitoring solutions should be adopted.

Alignment of the Right Talent to Risk Management

To better manage risk, the risk of competence and talent needs to be considered in connection with RM. New skills are likely to be needed, such as technological, risk factor data analytics, use of exploratory multivariate statistics, visualization tools and predictive analysis tools, and cyber and privacy skills, as well as critical thinking. Given the velocity of risk, a healthy level of intellectual curiosity will also be required (Ernst & Young 2018).

Summary

RM is much more than appointing a Chief Risk Officer and identifying or eliminating risks. It is also neither just a compliance issue based on rules (Kaplan and Mikes 2012) nor a reactive approach to risks. It is a culture, capabilities and practices put in place to identify and assess all types of risks and define priorities and strategies for eliminating

or mitigating them, in particular those highly likely, high-impact, and high-velocity risk events. The aim is to create or preserve value or avoid losses, aligned with the tone set by the defined risk appetite and tolerance.

Risk should be managed to achieve strategy and business objectives, rather than as purely individual risks (COSO 2017), but the potential impact of external risks should not be ignored (Kaplan and Mikes 2012). Different analytic approaches should be applied to preventable and non-preventable risk events. The implementation of new technologies and embedded RM systems makes risk identification, evaluation, prioritization, and monitoring more effective. Conducting continuous RM on a real-time basis is a high priority in the current hyper-volatile and hyper-connected environment, to ensure an agile approach to predict and respond to increasingly high-velocity risks.

Introduction

Corporate Social Responsibility (CSR) and Risk Management consist two relatively modern developing trends in business administration, which are not irrelevant and independent from each other. CSR is a strategic issue for every big corporation worldwide since the interest shown by both consumers and investors is big. Proportionally, dealing with corporate risk demands the occupation of specialized workforce since it is commonly acceptable that a good corporate fame could be destroyed easily in seconds due to environmental omissions and social oversights in the era of globalization. Thus, Risk Management and CSR are fields that attract the interest of managers, investors, banks, media, consumers, and rest stakeholders of modern firms and their in-between interactions could be examined bearing in mind the needed course towards sustainability for every company.

Risk Management and Globalization

Globalization has created an environment with many chances for entrepreneurship, although it is characterized by complexity, uncertainty, and riskiness. It seems that globalization has operated as catalyst for the increase of risk factor in

international business because (a) the enormous international competition has created very big group of companies that are consisted by several unlike units which do not know how to cooperate with consistency, (b) the velocity of spread for information, corporate scandals and rumors, is remarkable due to technology leapfrogging, and (c) the managing of huge organizations is often based on a central system of administration that misses local particularities (Kytte and Ruggie 2005: 5–7).

Thus, there have been formed corporate groups with interdependencies and hidden weak points among their affiliate companies, which are aggregated in a complex global business environment where uncertainty challenges decision-making process. The network-based operating models must include all stakeholders to develop a complete risk management system. These stakeholders have the means to achieve greater level of connectivity nowadays than in recent past, and finally additionally to consumers and investors, stakeholders like employees, nongovernmental organizations, local communities, politicians, regulators, suppliers, plus media create a complicated system of stakeholders' relationship that every modern company has to manage knowing that this equals with risk management (Kytte and Ruggie 2005).

From a corporation point of view, a social or environmental risk comes up from its own behavior or from other's actions who are somehow involved with it; thus, a sort of direct or indirect responsibility could be attributed to the corporation. Stakeholders could detect these points of friction between their interests and companies interests and they will try to press the firm for behavioral changes. These points of friction should be treated as vulnerabilities for the company itself, and thus, this kind of social risk should be included in decision-making. A well-established CSR policy that practically improves corporate processes and functions could be a mechanism to mitigate disputes between a company and its stakeholders.

Companies in the USA, Europe, and Japan have already a good knowledge of their stakeholders. However, nowadays, their networks are

global and often the central administration ignores the interests, the sensitivities, and the interests of specific groups of stakeholders. Possibly such points of friction can arise where there are political jurisdictions with weak regulatory frameworks and means of enforcement, increased fraud and corruption, and poor provision of social services. As bigger and more well-known a firm is, the better for a stakeholders' group to be opposed and bring their issues in public. The idea of civil society covers the existence of voluntary and not-for-profit organizations, philanthropic institutions, nongovernmental organizations (NGOs), activists' groups, community groups, local clubs, etc., that communicate each other make alliances or they maintain opposed interests and even they compete to influence more than other stakeholders the same company. In any case, the possibility for protests, boycotts, negative assessments for a company in social media, etc., are examples of choices available for civil society to apply pressure (Kytle and Ruggie 2005).

CSR Dimensions

The Kennedy School of Government has defined CSR to *"encompass not only what companies do with their profits, but also how they make them. It goes beyond philanthropy and compliance to address the manner in which companies manage their economic, social and environmental impacts and their stakeholder relationships in all their key spheres of influence: the workplace, the marketplace, the supply chain, the community and the public policy realm."* (Kytle and Ruggie 2005: 9).

There is a debate regarding the influence of CSR on a company's value, stocks performance, social capital, brand capital, and marketing. Researchers and businesspeople find evidences that are controversial and contradicted. However, it seems that significant criticality is detected on the factor of communication between a company and its stakeholders. More or less a well-communicated CSR policy could yield more benefits than a more complete CSR policy with poor communication side (Albuquerque et al. 2019:

4453). CSR operates as a product differentiation strategy and should be influenced more by consumers concerns and ideas than by investors. Projects that enhance company's CSR fame will reduce the cost of equity in comparison with similar projects. Investing in companies with CSR policy of high-level limits the total riskiness of a portfolio (Albuquerque et al. 2019). Belo et al. (2012) support that companies with significant spending in brand capital, based on advertising spending, have lower stocks returns than companies that show defiance to brand capital. However, the same researchers have found that companies with more robust brand capital have higher average stock returns of 5.2% annually and finally they conclude that spending in both brand capital and physical capital shows instability. Larkin (2013) has found that companies that maintain high brand perception have higher debt capacity and resilience in periods with financial frictions that support the idea that a strong brand value limits company's risk. Lins et al. (2017) support that companies with significant social capital, based on CSR assessment, have significantly higher stock returns during the financial crisis of 2007–2009. They highlight the critical parameter of trust between these companies and their stakeholders, which comes as result of intense investments in social capital, concluding that CSR policies are a risk management tool.

Risk Management in Depth

Every company when thinking risk management should consider the concepts of threats, vulnerabilities, controls, and countermeasures. There are some factors that operate as threats for a company's course to robustness, for example, Internet hacking. Threats could be either catastrophic, random, and unpredictable like a natural disaster that could destroy critical infrastructure or slow burn that burden company's operation day by day like climate change or the rise of a new service that enters the market. The next step is a company to detect which parts of itself are vulnerable to the recognized threats. A sector in

vulnerability status could be an unstable corporate intranet. Whether the threat of Internet hacking meets the vulnerable intranet, there is a risk. In that case, a company should employ control and countermeasures to assess the vulnerability on time, to take precautionary measures by installing firewalls for example and even create a specialized IT team to take over the situation in case of a cyber-attack (Kytle and Ruggie 2005).

The mathematical equation of Risk Management could be described like below:

$$\text{Social Risk} = \text{Threat} \times \text{Vulnerability}$$

where $\text{Threat} = \text{Stakeholder} \times \text{Issue}$

We could recognize five general kinds of risk: (a) technological, (b) economic, (c) political, (d) environmental, and (e) social. Technological factor has proved to be a key element for modern competition. Technological risk embraces a wide range of risks relevant to threats to automated systems, Internet, R & D, production lines, usage of energy, etc. and chief information officer (CIO) is liable for it. Economic risk is about preservation of profit and development rates, stock price course, shareholders' interests, etc. and chief financial officer (CFO) is liable for it. Political risk is complex especially for international organizations because factors like geo-politics interfere and demand from a Chief Executive Officer (CEO) to keep balances among governments and political parties. Environmental risk involves issues like climate change, carbon emissions, waste management, and a Health, Safety and Environment Manager could be responsible for it, etc. Nowadays, the current legal framework for environmental preservation is complicated since there is national and international legislation like in EU, regulations that accrue from international organizations and states alliances, several certifications, prizes, fines, etc.

Social risk comprises points of friction between a company and at least one of its stakeholders. This conflict of interests has as a result the reaction from stakeholders' end, which could be expressed with the application of pressure to

vulnerable areas for a company like its reputation. Social risk involves at least a stakeholders' group and could maintain on parallel another attribute, for example, an environmental risk could transformed to a social risk finally. The same could apply with a technological risk when new advanced production machines fail and cause accidents at workplace, for example. An issue of corruption with the involvement of a governmental officer could also become a social problem mirroring the corrosion in civil servants and their entanglement with private sector (see Fig. 1 below). Usual social problems are related to accident rates, environmental issues, discrimination at workplace, etc. A social problem has the power to extremely affect a company's profits, and thus, the rise of such an issue could imply changes in multiple sides of its operations like public relations, human resources, supply chain, marketing policy, etc. In general, as the phenomenon of civil society is getting stronger as people worldwide improve their educational level and societies approach closer democracy, companies should learn to respect sensitive issues and invent ways to deal with them by admitting, explaining, and correcting their actions.

Stakeholders as the Link Between CSR and Risk Management

There are three parameters of CSR that highlight the link between it and risk management: (a) CSR is a business need especially as a corporation is extending and is going internationally, (b) CSR spending is not a luxury or an optional activity, and (c) CSR should be connected with the core activities of a firm in order to be substantial (Kytle and Ruggie 2005) and such CSR is categorized as strategic CSR because it consists a strategic decision for an organization that decides to apply CSR principles over its functions and expects significant benefits from such strategy (Werther and Chandler 2006). CSR policy is a cornerstone for a successful risk management because it embraces the stakeholders' relationships, recognizes sensitive issues for them, receives the feedback from

**Risk Management
(Environmental Risk
and Social Risk) and CSR,**

Fig. 1 The interconnections among risk types reveal that all of them could have at least dual attribute, mainly the social attribute among others since they could affect society and cause social concerns

the interaction of the company with them, and finally operates as a countermeasure for social or environmental risk (Kytte and Ruggie 2005).

Especially regarding international firms, a corporate CSR policy supports corporate risk management because it (a) augments information, knowledge, and intelligence about what these risks are and (b) provides useful means to face them. **The key element regarding CSR and risk management is the correct recognition of stakeholders and the proper management of stakeholder relationship** (Kytte and Ruggie 2005).

When there are harmful effects for a society due to a company's actions, stakeholders react by applying punishments to it like boycotts or badmouthing, or abrogating business agreements with it. Godfrey (2005) support that stakeholders are used to be more stringent when the harmful side effects of a company's operation are accompanied by bad intentions. Active members of our civil society pay attention to the existence of mens rea and the existence of a well-established CSR policy could be proof of the lack of it. In this case, we could claim that the insurance effect has worked through the mitigation factor (Godfrey et al. 2009: 428).

The group of stakeholders is divided into two parts, primary and secondary stakeholders. As primary stakeholders are categorized these

subgroups of stakeholders that have direct relations and activities with a company. Due to that fact, they maintain legitimate claims on the company and leverage to apply strong legal pressure. On the other side, secondary stakeholders do not have direct exchanges with a company; thus, they cannot apply initially any legal or utilitarian power to it. A CSR program that targets to primary stakeholders is more likely to be considered as a continuation of business between the two parties. Such CSR activities create exchange capital among a company and its primary stakeholders and empower their trust and bonds. A CSR program that focuses on secondary suppliers, like civil society, creates moral capital since the germane activities cannot be seen so obviously as utilitarian in favor of company's side in order to serve its financial targets (Freeman et al. 2009; Godfrey et al. 2009).

CRS Benefits Risk Management

There is an interesting dialogue with scientific and business reasoning regarding the positive side effects of CSR in risk management, which embraces supply chain risk, regulatory risk, product and technology risk, litigation risk, physical risk, reputational risk, etc. (Starks 2009). Consequently, these interactions could affect a firm's

cost of capital. Benabou and Tirole (2010) found that companies with rich CSR history maintain a lower systematic risk exposure. Albuquerque et al. (2019) support that companies with robust CSR policy achieve a product differentiation strategy and aftermath a lower price elastic demand thus lowers systematic risk. Other researchers have focused on the interaction between a firm's CSR and bond credit ratings as indicators of firm's risk. There have not found strong elements that prove a direct relationship between a strong Corporate Social Performance (CSP) and credit ratings in general, but there are indications that in EU, in countries with advanced CSR mentality, companies with strong CSP enjoy improved credit ratings (Gillan et al. 2020). Jagannathan et al. (2017) claim that risks related to nature and society could have big impact on company's environment, which could be unusual, and thus, there may not be available the necessary experience to tackle them by a firm's side. Therefore, especially investors pay attention to these risks. Especially after the Paris Agreement in 2015, there has risen a strong belief that a successful CSR policy with strong CSP limits corporate risk (Hoepner et al. 2016). Consequently, funding organizations and banks examine with high interest Environmental, Social and Governance (ESG) criteria before funding a new project or provide a corporate loan.

CSR has a lot of advantages for a company since it produces reputational capital, manages reputational risk, and improves its performance by improving resources management and accumulates knowledge and information intelligence from stakeholder relationship management. The resultant reputational capital stock is useful for a company as a launch pad for new initiatives and acts as a buffer in periods of crises (R. Lizarzaburu 2014). Several studies support that CSR benefits risk management efforts of a firm by providing an insurance-like protection (Lins et al. 2017), which is extremely necessary in crisis and recession periods. It seems that especially CSR programs that are related to society and environment bring closer consumers to environmentally and socially responsible firms. It seems that most CSR programs suggest a way to preserve Corporate

Financial Performance (CFP) rather than produce it. CSR policy could increase the social capital and improve the brand of a firm preserving economic value probably without generating economic value (insurance effect), and this is valuable too, especially during difficult times (Godfrey et al. 2009: 426–427).

Corporations with intense CSR footprint achieve to maintain a better image amid a financial depression when overall trust in firms is expected to be low. CSR in general empowers the trust among a firm and its stakeholders and augments its social capital. The experience from the recent depression of 2008–2009 has offered evidences for this reasoning although this connection predates the depression (Fitzgerald 2003; Lins et al. 2017). Furthermore, the experience from the pandemic of Coronavirus and the birth of an ad hoc CSR type called Critical CSR corroborates this mutually beneficially relationship. Critical CSR as a hybrid between strategic and tactical CSR has served as a shield for the protection of employees and other stakeholders from COVID-19. The protection measures for employees like the provision of the possibility for work from home and the implementation of supportive CSR actions like the donations of equipment and money to hospitals keep a strong bond among firms, employees, governments, and citizens. Finally Critical CSR has operated as a guide for a successful risk management in coronavirus era (Panagiotopoulos 2021).

Reputational risk is one of the risks that a company could face due to malfeasance and the resultant social reaction. This risk consists a significant reduction in company's good fame, a decline in its popularity and the development of opposite feelings and impressions from consumers and civil society in general, which threatens the corporate value. Vizcaino-González (2010) has distinguished two types of reputational risk, the immediate situational reputational risk and the expected reputational risk. The first type concerns facts that are unexpected and a company must deal with them without preparation and available time, like environmental accidents and physical disasters. The second type embraces cases with a

negative footprint to environment and society, but there is time for company's management to deal with it, communicate it to stakeholders, and make corrective actions to mitigate the negative impact (Vizcaíno-González 2010).

Finally, CSR leads to Socially Responsible Investments (SRI) and SRI entails investments and operations of lower risk. We could summarize that a complete CSR policy can assist a company to:

- Exploit efficiently all its resources
- Assure a working environment of high Health, Safety, Environment (HSE) standards
- Better performance in stock market either in normal conditions or amid a period of crisis like a pandemic or a financial depression (Duchin et al. 2010).
- Avoid penalties and fines related with environmental issues, local legislation, etc.
- Create brand loyalty
- Enhance brand recognition based on green marketing
- Approach local communities and overcome difficulties through channels of communication
- Easier funding through banking sector due to Environmental, Social, and Governance (ESG) criteria (Sciarelli et al. 2021).

Summary

CSR could contribute to two categories: (a) money saved and (b) money earned (Panagiotopoulos 2020). Risk management entanglement with CSR directs us into money saved field. A firm can avoid fines and penalties, boycotted products, overexploitation of resources, scandals, and rumors. Furthermore, in case of special circumstances like an accident at the workplace, a company with developed CSR policy could be treated with less stringent attitude by its stakeholders like its customers. Furthermore, amid period of recession, there are researches with the inference that customers prefer to support

companies with good social profile. The same applies in stock market where the share of companies with advanced CSR policy performs better than those companies that have not, especially during a period of crisis.

There are three parameters of the globalized business system that affect CSR and its correlation with risk management: (a) networked operations, value chains and global economy, (b) enhancement of international networks of stakeholders, and (c) dynamic tension between and among stakeholders (Kytle and Ruggie 2005: 6). Gone is the era when a company could easily screen the edges of its value chain and control it. Globalization has brought new business opportunities and risks since international value chains are extended in several countries, with several subcontractors, sub-supply chains, and remote regions. As the multitude of such partners is augmented, each new part of its chain aggregates its own set of local stakeholders. In globalization era with a fierce international competition, a ripple and abnormality in any spot in this system of interconnected chains like labor practices or polluting accidents could be used against a company's integrity with a hit exactly in the core of its management.

There is a plethora of evidences that something has changed regarding environmental and social issues in multidimensions and sides. The existence of global issues has given the ground and the reasoning for the turn of spotlight to companies. Civil society has developed expectations for companies. Companies have developed CSR programs. Banks and consulting firms have designed ESG criteria and evaluate firms with them. Governments and coalitions of states have established ambitions, environmental targets for decarbonization, and zero emissions. The change is not unilateral. The whole world has changed and the nexus of risks for companies have changed too. The dialogue for the tangible advantages of CSR to companies will be continued; however, the interconnection between risk management and CSR either tangible or intangible remains critical for the

sustainable course of a modern company. Firms that will continue to ignore their stakeholders cannot understand in depth their risk management issues, and they cannot effectively protect their survival and progress. CSR and risk management have not only been interconnected each other, but mainly they cultivate the ties between corporations and civil society for a better common future.

Risk Management and CSR

Rossella Leopizzi

Ionic Department in Legal and Economic System of Mediterranean: Society, Environment, Culture, University of Bari Aldo Moro, Taranto, Italy

Definition

The risk is defined as the possibility that events will occur and affect the achievement of strategy and business objectives.

To mitigate risk, companies have to develop risk management systems. Risk management systems fundamentally aim to address uncertainty in the marketplace. Their primary goal is to create controls and countermeasures that minimize or eliminate the disruption, loss, or damage to business operations and shorten the recovery time from an unwanted event, thereby reducing its impact on business.

Specifically, risk management is the process of identifying, assessing, and controlling threats to an organization's capital and earnings. These threats, or risks, could stem from a wide variety of sources, including financial uncertainty, legal liabilities, strategic management errors, accidents, and natural disasters.

The traditional risk management process is developed as follows:

- Establish a causal relationship between the presence of a threat or a group of threats and a specific undesirable outcome.
- Identify elements of the business process that are at risk of experiencing the undesirable outcome. In this sense, the term "vulnerability" is often used to describe this state. When a threat meets potential vulnerability, the business element or process is deemed to be "at risk."
- Take action to eliminate or reduced the identified risk factors, thereby reducing the presence of the associated undesirable outcome.

Corporate social responsibility is related to corporate risk management through two means:

by providing intelligence about what those risks are and by offering an effective means to respond to them. The key to both is more effectively "managing stakeholder relationship."

Introduction

Considering the increasing complexity of market and of doing business, risk management has become a fundamental part of internal control in order to identify, measure, and assess the different kinds of risks that a company has to face.

Risk management has influenced research in the area of business and society. One of the dominant themes in the field has been the study of the relationship of corporate social responsibility (CSR) to financial performance. A subset of these studies began to look at the relationship of CSR to risk. Early studies in the field were concerned about adjusting returns for risk in order to make returns comparable from firm to firm. Spicer (1978), however, did look directly at the CSR-risk relationship and found evidence for a negative correlation between the two: as CSR increased, risk decreased. Risk was sometimes included as a control variable and sometimes as a dependent or independent variable. Orlitzky and Benjamin (2001) provided a very good meta-analytic review of the literature on CSR-firm risk and found support for a negative relationship between CSR and risk.

The argument relating risk management to CSR is fairly straightforward. In fact, Bowman's (1980) article, which has spurred so much research on risk in strategic management, specifically mentions corporate social responsibility as a means for reducing business risk. According to this argument, firms with proactive CSR engage in managerial practices like environmental assessment and stakeholder management (Wood 1991) that tend to anticipate and reduce potential sources of business risk, such as potential governmental regulation, labor unrest, or environmental damage (Orlitzky and Benjamin 2001). Unfortunately, the work in the area of business and society seems to have largely ignored the advances within strategic management, which has moved to a more refined

Type	ESG-related risk or opportunity	Environmental	Social	Governance
Strategic	• Shifting customer preferences toward products that are manufactured with ethical supply chains		■	
	• Growing Investor Interest in ESG issues, resulting in proxy voting against the company on a range topics (e.g., diversity, deforestation and human rights)	■	■	■
Operational	• Increased cost of raw materials due to sustainable forestry practice requirements	■		
	• Reduction of waste and raw material costs through improved manufacturing processes	■		
	• Changing weather patterns and increased natural disasters disturbing operations and business continuity	■		
Financial	• Reputation impacts and societal concerns due to a tax avoidance strategy and lack of tax transparency		■	■
	• Investment in local content to generate sustained and inclusive growth through economic diversification and employment opportunities		■	
	• Increased taxation from carbon tax regulation	■		
Compliance	• Enhanced reporting requirements for greenhouse gas emissions and energy usage	■		
	• Inaccurate or fraudulent disclosure of emissions resulting in fines and penalties and loss of consumer trust	■		■

Risk Management and CSR, Fig. 1 Example ESG-related risks or opportunities (by COSO)

conception of the relationship of risk to management generally, as well as of its measurement.

Furthermore, nonfinancial risk management is useful to achieve corporate responsibility and social responsibility goals (Wong 2013). In fact, nonfinancial risk management tends to minimize risks and the negative effects of unsustainable practices, such as penalties, not compliance, and so on (Porter 1985, 1991; Porter and van der Linde 1995; Welford 2000; Spedding and Rose 2008).

Typical categories of risk include strategic, operational, financial, and compliance. Some organizations may include a separate category for “sustainability” or “reputational” risks. However, these risks can usually be grouped in other risk categories (e.g., climate-related risks are often operational or financial in nature). Further, reputational implications are often an impact from another type of risk, rather than a risk in and of itself (e.g., reputational damage resulting from an environmental incident or pollution). In addition, many ESG-related risks are not entirely new but rather represent an additional source to an existing risk or compound the risk’s impact or likelihood of materializing. For example, climate change

impacts often increase the risk of raw material cost fluctuations, which is an existing risk for many entities (see Fig. 1 by COSO 2018).

Key Issues

Since the early 2000s, several industry and government bodies have expanded regulatory compliance rules that scrutinize companies’ risk management plans, policies, and procedures. In an increasing number of industries, boards of directors are required to review and report on the adequacy of enterprise risk management processes. As a result, risk analysis, internal audits, and other means of risk assessment have become major components of business strategy.

Risk management standards have been developed by several organizations, including the National Institute of Standards and Technology and the ISO. These standards are designed to help organizations to identify specific threats, assess unique vulnerabilities to determine their risk, identify ways to reduce these risks, and then implement risk reduction efforts according to organizational strategy.

The ISO 31000 principles, for example, provide frameworks for risk management process improvements that can be used by companies, regardless of the organization's size or target sector. The ISO 31000 is designed to "increase the likelihood of achieving objectives, improve the identification of opportunities and threats, and effectively allocate and use resources for risk treatment," according to the ISO website. Although ISO 31000 cannot be used for certification purposes, it can help provide guidance for internal or external risk audit, and it allows organizations to compare their risk management practices with the internationally recognized benchmarks.

The ISO recommended the following target areas, or principles, should be part of the overall risk management process:

- The process should create value for the organization.
- It should be an integral part of the overall organizational process.
- It should factor into the company's overall decision-making process.
- It must explicitly address any uncertainty.
- It should be systematic and structured.
- It should be based on the best available information.
- It should be tailored to the project.
- It must take into account human factors, including potential errors.
- It should be transparent and all-inclusive.
- It should be adaptable to change.
- It should be continuously monitored and improved upon.

The ISO standards and others like it have been developed worldwide to help organizations systematically implement risk management best practices. The ultimate goal for these standards is to establish common frameworks and processes to effectively implement risk management strategies.

These standards are often recognized by international regulatory bodies or by target industry groups. They are also regularly supplemented and updated to reflect rapidly changing sources of

business risk. Although following these standards is usually voluntary, adherence may be required by industry regulators or through business contracts.

All risk management plans follow the same steps that combine to make up the overall risk management process:

- Risk identification. The company identifies and defines potential risks that may negatively influence a specific company process or project.
- Risk analysis. Once specific types of risk are identified, the company then determines the odds of it occurring, as well as its consequences. The goal of the analysis is to further understand each specific instance of risk and how it could influence the company's projects and objectives.
- Risk assessment and evaluation. The risk is then further evaluated after determining the risk's overall likelihood of occurrence combined with its overall consequence. The company can then make decisions on whether the risk is acceptable and whether the company is willing to take it on based on its risk appetite.
- Risk mitigation. During this step, companies assess their highest-ranked risks and develop a plan to alleviate them using specific risk controls. These plans include risk mitigation processes, risk prevention tactics, and contingency plans in the event the risk comes to fruition.
- Risk monitoring. Part of the mitigation plan includes following up on both the risks and the overall plan to continuously monitor and track new and existing risks. The overall risk management process should also be reviewed and updated accordingly.

Future Directions

As regards the field of risk, since 2013, the European Parliament, in the resolutions of 6 February 2013, has acknowledged the importance of business divulging information on sustainability such as social and environmental

factors, with a view to identifying sustainability risks and increasing investor and consumer trust.

In particular, the subsequent EU Directive 2014/95 represents an important step toward the spread of CSR throughout European Countries. It indicates “nonfinancial and diversity information” to be disclosed by large companies in their annual report or in a separate document.

According to Directive 2014/95/EU, the non-financial information (NFI) to be included is essentially “information to the extent necessary for an understanding of the undertaking’s development, performance, position and impact of its activity, relating to, as a minimum, environmental, social and employee matters, respect for human rights, anti-corruption and bribery matters, including:

- a brief description of the undertaking’s business model;
- a description of the policies pursued by the undertaking in relation to those matters, including due diligence processes implemented;
- the outcome of those policies;

- the principal risks related to those matters linked to the undertaking’s operations including, where relevant and proportionate, its business relationships, products or services which are likely to cause adverse impacts in those areas, and how the undertaking manages those risks;
- non-financial key performance indicators relevant to the particular business.”

Furthermore, recently, the Committee of Sponsoring Organizations of the Treadway Commission (COSO) and the World Business Council for Sustainable Development (WBCSD) have partnered to publish a guidance to help entities better understand the potential effects of sustainability risks and to manage and disclose them effectively (COSO 2018).

As represented in Fig. 2 by the COSO, the guidance provides 5 components and 20 principles and offers, at the same time, a practical approach to entities using other risk management frameworks, such as ISO 31000 or entity-specific risk management frameworks.

8. INCORPORATING SUSTAINABILITY IN PRUDENTIAL REQUIREMENTS		
Work towards incorporating climate risks into institutions' risk management policies and on the potential calibration of banks' capital requirements in the Capital Requirement Regulation and Directive to take into account climate change-related risks while safeguarding financial stability and ensuring coherence with the EU taxonomy.	Issue under discussion in the on-going legislative procedure	2018-2019
The Commission will invite the European Insurance and Occupational Pensions Authority to assess the impact of prudential rules for insurance companies on sustainable investment	(NL)	Q3 2018

Risk Management and CSR, Fig. 3 Incorporating sustainability in prudential requirements (by EC, Action Plan: Financing Sustainable Growth)

Also the European Commission, in its action plan, financing sustainable growth, has given a growing importance to incorporate sustainability in the process of risk management. In this direction, the European Commission will explore the feasibility of the inclusion of risks associated with climate and other environmental factors in institutions' risk management policies and the potential calibration of capital requirements of banks as part of the Capital Requirement Regulation and Directive. The aim would be to take into account such factors, where this is justified from a risk perspective, to safeguard the coherence and effectiveness of the prudential framework and financial stability. Any recalibration of capital requirements, based on data and the assessment of the prudential risk of banks' exposures, would need to rely on and be coherent with the future EU taxonomy on sustainable activities.

In Fig. 3, the work plan of this specific initiative set out by this action plan is represented:

Definition/Description

The expression “role of the private sector in sustainable development” refers to the role of for-profit organizations in the creation, adoption, development, and execution of public policies that promote environmental, social, and economic aims. The private sector has a critical role in sustainable development in general and the United Nations’ Sustainable Development Goals (SDGs) in particular (UN General Assembly 2015). Arguments in support the active role of the private sector in sustainable development include the improvement of innovation and technology, the provision of resources and jobs, the adoption of sustainable business models, the significance of the private sector in addressing environmental issues, and the capability, know-how, leadership, and efficiency that businesses offer. Although the degree of private sector participation in sustainable development varies because of business’s strategic decision-making, many businesses have realized the importance of the matter and the opportunities it represents and have taken measures to involve themselves in such programs.

Introduction

The development of societies can be analyzed from different perspectives. What in one view is

a “developed society” may be “underdeveloped” in another. Development is traditionally associated with economic progress. Other factors, however, have gained importance in both the definition and perception of what constitutes a developed society. For instance, environmental issues, poverty levels, and broader social problems such as inequality and injustice have become essential aspects of assessing development.

The conventional approach to development is associated with modernization theory (Baker 2006). This theory is derived from a broad concept of development which associates development with the idea of modernization: “To be modernized, a society has to become more technically sophisticated and urbanized and to make increased use of markets for the distribution of economic goods and services” (Baker 2006). The concept of sustainable development challenges this conventional approach to development – the modernization theory (Baker 2006). Sustainable development, by way of contrast, conceptualizes development more comprehensively. Sustainable development extends beyond economic, market-led growth in the near term, which favours private for profit. It extends the concept of development to include attention to the impacts of economic development on the social and natural environments and considers future generations’ interests as well (Sheehy and Farneti 2021).

The private sector is directly linked with development. It is a major economic actor in both developed and developing countries. The private sector, for instance, provides nine out of ten jobs in emergent nations (Center for Strategic & International Studies 2018). The extent to which the private sector should be involved in sustainable development, however, is a contested matter as some parties prefer state or nonprofit sector to have a greater share of resources and responsibilities.

In recent years, especially after the 2007–2008 global financial crisis and the subsequent definition of the SDGs which combined to bring attention to the issues, the private sector has been more engaged with sustainable development. Governments and international organizations have turned to the private sector to increase available funds

and obtain relevant know-how to address development issues (Scheyvens et al. 2016). Additionally, a rising number of private organizations have adopted sustainable development measures. As set out in the United Nations (UN) Global Compact, a public-private initiative of the UN, “[t]he defining feature of these organizations is a growing desire to link their policies and behaviour – rooted in accountability and transparency – with broader sustainable development priorities and objectives. Fundamentally, they recognize that what is good for societies and the planet is also good for business over the long term” (UN Global Compact 2014). Private organizations have realized that basic resources such as water, energy, and minerals are different from regular fungible commodities transacted in markets (UN Global Compact 2014). The private sector, therefore, is developing business models with broader social, economic, and environmental values in mind while seeking commercial success (Scheyvens et al. 2016).

“Private Sector” and “Sustainable Development”

Understanding the role of the private sector in sustainable development requires the identification of the concepts of “private sector” and “sustainable development” independently. The concept of the “private sector” is associated with businesses (Mio et al. 2020) or for-profit organizations (UN Global Compact 2014). It encompasses private organizations of different sizes – small, medium, and multinational companies – in various industries, such as food, mining, and pharmaceutical (Blowfield 2012; Gentry and Esty 1997). In essence, any organization that is not governmental body and is profit-focused is considered “private sector.”

“Sustainable development” is a contested and dynamic concept (Baker 2006; Mio et al. 2020; Sheehy and Farneti 2021). It is contested because there are different approaches to sustainable development, and it is dynamic because it is an

ongoing process where the desirable characteristics and targets change over time and space (Baker 2006). Baker explains that “sustainable development” is a model that “seeks to reconcile the ecological, social, and economic dimensions of development, now and into the future, and adopts a global perspective in this task. It aims at promoting a form of development that is contained within the ecological carrying capacity of the planet, which is socially just and economically inclusive. It focuses not upon individual advancement but upon protecting the common future of humankind” (Baker 2006).

Sheehy and Farneti conceptualize “sustainable development” more precisely as follows: “Its scope is primarily public international bodies and nation-states with multinational enterprises involved through initiatives such as the United Nations Global Compact. It is focused on public international development policy encompassing initially environmental goals but expanding to include social and economic goals” (Sheehy and Farneti 2021). “Sustainable development,” therefore, is concerned with broader public policies for both public and private organizations, public policies such as the SDGs. It is not designed to provide guidance for private organizations: that is the task of corporate social responsibility (CSR) and “corporate sustainability” (Sheehy and Farneti 2021).

Consequently, the role of the private sector in sustainable development refers to the role of businesses and for-profit organizations in the creation, adoption, development, and execution of public policies that promote environmental, social, and economic purposes. Today, the role of the private sector in sustainable development is captured by association with the SDGs.

Sustainable Development Goals (SDGs)

The SDGs are the culmination of decades of gatherings between world leaders and the private sector in different UN conferences: Rio de Janeiro in 1992, Johannesburg in 2002, and Rio de Janeiro

in 2012 (Rio +20) (Scheyvens et al. 2016). The main antecedents of the SDGs are the Global Compact, which engages businesses to identify and promote corporate practices built upon universal principles (Ruggie 2002), and the Millennium Development Goals (MDGs), which set eight goals promoting sustainable development (Mio et al. 2020).

In 2015, the UN adopted the 2030 Development Agenda and the SDGs (UN General Assembly 2015). The Agenda refers to a global “plan of action” to achieve the SDGs by 2030 (Mio et al. 2020; Rashed and Shah 2021; Van Zanten and Van Tulder 2018). The 17 SDGs are no poverty; zero hunger; good health and well-being; quality education; gender equality; clean water and sanitation; affordable and clean energy; decent work and economic growth; industry, innovation, and infrastructure; reduced inequality; sustainable cities and communities; responsible consumption and production; climate action; life below water; life on land; peace, justice, and strong institutions; and partnerships to achieve the goals.

These 17 SDGs address the “triple bottom line” – social, environmental, and financial aspects – of development (Scheyvens et al. 2016). The SDGs, as Van Zanten and Van Tulder note, “are more than a wish list. They are an intergovernmental agreement – based on multi-stakeholder engagement processes – that urges companies to help solve developmental challenges” (Van Zanten and Van Tulder 2018).

Of particular importance is Goal 17, “partnership to achieve the goals,” because it expressly incorporates the participation of other actors, including the private sector, in achieving the SDGs and, consequently, global sustainable development. One of the targets of Goal 17 is to “[e]ncourage and promote effective public, public-private, and civil society partnerships, building on the experience and resourcing strategies of partnerships” (Florini and Pauli 2018).

The SDGs constitute the most important global effort to include businesses in the deliberation, development, and adoption of sustainable

development. According to Scheyvens et al., “[t]he close involvement of the private sector in the SDG process reflects a conscious shift in the past decade that has seen the private sector become more entwined in the world of development policy and planning” (Scheyvens et al. 2016). Although the SDGs are addressed to all actors in society – governments, civil society, NGOs, and nonprofit organizations – the private sector is a central actor in the achievement of the SDGs (Mio et al. 2020).

Importantly, there are other non-UN initiatives promoting the private sector participation in sustainable development. This list includes the CERES Principles, the ICC Business Charter for Sustainable Development, and the OECD Guidelines for Multinational Enterprises (Scheyvens et al. 2016).

What Is the Role of Private Sector in Sustainable Development?

The private sector has a critical role in sustainable development in general and the SDGs in particular (Mio et al. 2020; UN Global Compact 2014; Van Zanten and Van Tulder 2018). The main arguments that explain why the role of the private sector is critical in achieving sustainable development are the following:

1. Innovation and technology (Denoncourt 2020; Garcia 1997; Rashed and Shah 2021; Scheyvens et al. 2016). Businesses, unlike other actors, have the economic capacity and the competitive drive to innovate (Denoncourt 2020; Garcia 1997). Innovation and cutting-edge technologies are fundamental to address unmet needs that prevent sustainable development.
2. Provision of resources and jobs (Scheyvens et al. 2016; Rashed and Shah 2021). The private sector is the primary source of employment and wealth, fundamental factors for the development of countries and the elimination of poverty.

3. Social entrepreneurship (Blowfield 2012; Garcia 1997). Beyond a generator of resources and jobs, the private sector can design business models that are both commercially viable and beneficial to the poor (Blowfield 2012).
4. Environmental matters (Rashed and Shah 2021; Shepherd and Patzelt 2017). Particularly, businesses can help preserve ecosystems, neutralize climate change, decrease environmental degradation and deforestation, improve farming practices, provide more access to freshwater, and maintain biodiversity (Shepherd and Patzelt 2017).
5. Capability (Gomez-Echeverri 1997; Rashed and Shah 2021; Sachs 2012). The private sector provides the worldwide reach and massive capacity required to reach large-scale solutions (Sachs 2012).
6. Know-how (Berrone et al. 2019; Rashed and Shah 2021; Scheyvens et al. 2016). Businesses have technical, specialized expertise and knowledge related to specific industry sectors that can be used to improve sustainable development (Berrone et al. 2019).
7. Leadership (Scheyvens et al. 2016). The trend is that businesses have a more directive and governance function in global sustainable development (Scheyvens et al. 2016).
8. Efficiency (Faulkner 1997; Panayotou 1997). According to Faulkner, “[t]he private sector has financial, technological, and management resources as well as a proven track record of providing lower production costs, delivering services more efficiently, maintaining capital equipment at a higher standard, making decisions faster than public bureaucracies, and offering consumers greater choice” (Faulkner 1997).

The degree of involvement of the private sector in sustainable development may vary. Michael Blowfield argues that the private sector can be considered a development tool or a development agent (Blowfield 2012). As a development tool, businesses have a positive impact on development due to their economic contribution. As development agents, they are responsible for enabling or preventing development. “And whereas the

business-as-usual approach to development emerges from managerial calculations related to costs, returns and competition, business as a development agent is also motivated by stakeholder concerns, pressures and demands” (Blowfield 2012). Although the private sector is not obliged to be a development agent, many businesses have adopted this role voluntarily (Blowfield 2012; Scheyvens et al. 2016).

The active role of the private sector in sustainable development does not undermine or replace the role of governments and other actors (Gomez-Echeverri 1997; Scheyvens et al. 2016). The role that these actors play in the achievement of sustainable development is, however, considered fundamental. For instance, under the SDGs, “businesses, governments and civil society actors are equally called upon to pursue a more sustainable path forward” (Scheyvens et al. 2016). Multiple authors have argued that the best, most efficient way to address the issues that hinder sustainable development is a partnership between the government and the private sector (Faulkner 1997; Gomez-Echeverri 1997).

Various examples of business engagement with the SDGs can be seen in studies such as Rahdari et al.’s study of sustainability in global supply chains (Rahdari et al. 2020) and Sheehy et al.’s study of the use of sustainability standards in retailers in the Asia-Pacific (Sheehy et al. 2021).

Summary

The role of the private sector in sustainable development refers to the role of private sector, for-profit organizations, in the creation, adoption, development, and execution of public policies that promote environmental, social, and economic purposes. The role of the private sector in sustainable development is generally associated with the 17 SDGs. It has been argued that the private sector plays a crucial role in achieving these goals. Several reasons substantiate this position. While today the private sector is not compelled to take steps toward sustainable development, many businesses have voluntarily adopted practices that

improve the “triple bottom line” of sustainability broadly conceived.

Definition

SA8000 is a voluntary international standard for auditable third-party verification issued by Social Accountability International (SAI), with the scope of advancing human rights at work.

Introduction

SA8000 is a voluntary international standard for auditable third-party verification issued by Social Accountability International (SAI), a global

nongovernmental organization founded in 1997 with the scope of advancing human rights at work. Today, the SA8000 Standard is the leading worldwide social certification standard for factories and organizations in the field of workers' rights and sustainable workplaces. The Standard is consistent with the provisions of international conventions, including the Universal Declaration of Human Rights, the International Labor Organization (ILO) conventions, and the UN Convention on the Rights of the Child. It also respects and supplements national labor laws around the world to secure ethical working conditions. The certification standard is applicable to every type of organization, regardless of its size, geographic location, or industry sector, for profit or nonprofit scope. Regular revisions are pursued, to ensure alignment with new and emergent human rights issues. At the end of 2018, over 4000 facilities across 62 countries were SA8000 certified. The Standard can help improve conditions relating to unsustainability that often derive from a global supply chains, making it possible to protect workers from a lack (or even absence) of laws as per what often prevails in developing economies.

History

In the 1980s, the phenomenon of globalization, the increasing relevance of corporate social responsibility (CSR) for the business world, and the growing demand for social justice expressed

by society led corporations to appreciate the need for improving their social and environmental accountability. In this period, voluntary disclosure of information on ethical, social, and environmental policies and practices spread, above all among large multinational enterprises (MNEs). The aim was to gain and maintain social legitimacy.

Even in the field of labor practices, leading firms began to adopt their own codes of conduct on a voluntary basis. However, because the provisions were heterogeneous across firms, different requests were directed to the supply chain from different firms, generating a confused situation or suppliers having to respond to nonconsistent technical audits from clients.

Moreover, the information disclosed by corporations – in the context of lacking independent assessments – were often considered unreliable (if not voluntarily manipulated) by stakeholders, and therefore missing their main objective to enhance the firm's reputation.

In this context, in 1994, the International Labor Organization (ILO) started a cooperative endeavor with the Council of Economic Priorities (CEP). CEP is a nonprofit research organization based in New York and London founded in 1969 and devoted to accurate and impartial analysis of the social and environmental accountability of corporations. The objective of the cooperation was to explore how to reduce the plague of child labor and it attracted the interest of important MNEs who were facing accusations in this respect. Starting from this, the initiative expanded towards the wider objective of improving working conditions through the elaboration of an international standard and involved representatives of managers and entrepreneurs, labor unions, and nongovernmental organizations (NGOs). On October 15, 1997, the standard SA8000 was first officially released by the Council on Economic Priorities Accreditation Agency (CEPAA) (which later on, in 2000, changed its designation to Social Accountability International), a multi-stakeholder nonprofit initiative, established by the CEP specifically to develop the standard. Since then, the standard has been regularly revised to maintain its leading role in a changing society. Superseding previous versions of 2001, 2004, and 2008, the

current version of the standard (the fourth) was released in 2014 (SA8000:2014).

SAI Mission and Governance

Today, SAI is a global multistakeholder standard-setting organization based in New York. Its mission is to advance human rights in workplaces. On its official website, it states “We envision a world where workers, businesses, and communities thrive together.” Consistently, SAI is committed to protecting the rights and dignity of workers through developing systems of accountability based on socially responsible standards.

The governance of SAI is based on two pillars: the Board of Directors and the Advisory Board. The Board of Directors – presently composed of 10 members – defines the main strategies of the organization and has responsibility for activities and operations. Its members have a very mixed background, coming from MNEs, NGOs, consulting firms, community interests, and governmental agencies. The Advisory Board provides directions for SAI's policies and has mainly a counseling role supporting the Board, with no responsibility for operations. It has a double soul, as approximately half of the members are affiliated with business (and some of them are currently directors in primary MNEs like Walt Disney, HP, Gucci, and Tata Steel), while the other half is affiliated with main stakeholders groups (e.g., NGOs, trade unions, socially responsible investing, governments, and academia). Both organs are supported by the Founders' Committee, comprising retired SAI Advisory Board members who have contributed exemplary services and who continue to provide their expertise, including attendance at meetings as nonvoting members.

It should be noted that SAI is the developer and publisher of SA8000, but it does not carry out auditing and certification itself. These services are performed independently by certification bodies, which have to first of all apply for accreditation. Social Accountability Accreditation Services (SAAS) is the only accreditation agency that evaluates, accredits, and monitors organizations entitled to certify the conformity of an organization to

SA8000. Emerging in 1997 as a department within SAI, since 2007 SAAS has been an independent nonprofit accreditation agency. Currently, there are only 29 accredited certification bodies entitled by SAAS to provide SA8000 certification.

Content of the SA8000 Standard and the Certification Process

The SA8000 Standard aims to provide a system of requirements to encourage organizations to apply, maintain, and develop socially acceptable and fair practices in the workplace. Compared to other accountability standards and codes designed to signal companies' commitment towards sustainability and social responsibility – like Global Compact, AccountAbility 1000 (AA1000) (see ► [“AA1000 Series of Standards, The”](#)), Global Reporting Initiative (GRI) (see ► [“Global Reporting Initiative”](#)), Fair Labor Organization (FLA) Workplace Code, and ISO 26000 (see ► [“ISO 26000 Standard”](#)) – SA8000 distinguishes itself because it is a certification standard (this means that the system has to be audited by an independent organization), it is an industry non-specific standard, and it extends to the whole supply chain of the certified firms (Gilbert and Rasche 2007; Sartor et al. 2016; Göbbels and Jonker 2003).

Indeed, SA8000 is an auditable certification standard for third-party verification modeled on ISO standards (Llach et al. 2015). Thus, for organizations to gain and maintain certification, they must comply with specific requirements,

integrating them into their management practices, but also demonstrating to be able to go beyond, adopting a management system directed towards continuous improvement of performance.

Even if the requirements in terms of workplace conditions and management system have to be met by organizations, certification is only available per specific worksite. This means that individual factories are monitored and certified for compliance with the Standard, rather than a company: to be certified, every facility must be audited.

The certification process is illustrated in Fig. 1. The first step in the SA8000 certification process is a management system self-assessment undertaken by the organization. SAI released a specific online tool called Social Fingerprint which helps to evaluate if an organization is ready to apply for certification. Social Fingerprints evaluates the maturity level of an organization management system in ten areas considered most critical to social performance (e.g., risk identification and assessment, monitoring, external verification, and stakeholder engagement), giving, as a result, an overall ranking on a scale from 1 to 5 and also identifying areas for improvement.

If the organization considers itself mature enough to pursue the certification, it selects one among the accredited certification bodies and starts the evaluation process. The certification body – after visiting the facility – generates a preaudit report with a list of corrective measures and improvements required to obtain certification. After the organization has put in place corrective actions, the actual certification audit takes place, verifying compliance with the Standard. If the

SA8000 Standard,
Fig. 1 SA8000
certification process

organization fits the requirements, it is granted SA8000 certification. Hereafter, periodic surveillance audits are conducted at least every 6 months. The certification expires after 3 years, and then facilities must be again subjected to the full certification process to become recertified.

The SA8000 requirements are mainly derived from principles expressed in international conventions such as the International Labor Organization Conventions, the United Nations Conventions on the Rights of the Child, and the UN Declaration of Human Rights. The Standard comprises three main documents:

- (a) The SA8000:2014 Standard presents the intent and scope of the standard itself, the normative elements and definitions adopted, and the social accountability requirements.
- (b) The SA8000 Performance Indicator Annex contains the minimum performance expectations of a SA8000 certified organization.
- (c) The SA8000 Guidance Document offers support for both organizations and auditors to interpret and implement the SA8000 requirements, providing examples and methods for verifying compliance.

The requirements of the Standard are grouped in eight issues, plus the obligation of a management system driving towards continuous improvement in all areas of the Standard:

- 1. Child Labor
- 2. Forced and Compulsory Labor
- 3. Health and Safety
- 4. Freedom of Association and Right to Collective Bargaining
- 5. Discrimination
- 6. Disciplinary Practices
- 7. Working Hours
- 8. Remuneration
- 9. Management System

For each requirement, the SA8000 Standard provides general principles of fair treatment of workers and minimum performance expectations.

It should also be noted that SA8000 also involves the supply chain, as the organization

shall conduct due diligence on all its suppliers, subcontractors, and subsuppliers to assure their compliance with the Standard. Here SA8000 plays the important role of ethical sourcing standard.

It is clearly stated that each certified organization shall also comply with local and national laws and, in case it is subjected to other requirements for the same issues addressed in the Standard, the most favorable provision for workers shall be applied. Given that the requirements of the Standard have the aim to ensure that basic workplace standards are met, normally the legal provisions applicable to companies in developed countries are far more restrictive, making certification of their local factories in a large part meaningless. Thus, certification is more important for two groups of companies: developed countries' firms with a global supply chain (as guarantees that all their suppliers comply with the Standard's requirements) and developing countries suppliers (as allows to demonstrate providing fair treatment of workers in their facilities, not risking the brand reputation of the client company).

The Certified Organization

In general terms, the SA8000 Standard is universally applicable to any organization, regardless of the profit or nonprofit scope and the industry, and in any country. However, it is recognized that in some specific circumstances, special challenges can arise in meeting all the Standard requirements due to industry norms and technical needs. Similarly, some countries can be considered unsuitable for hosting certifiable organizations if they do not offer enough guarantees for a reliable mechanism to enforce local laws, or if they have laws acting explicitly against the Standard.

Thus, to reduce the reputational risk of the certification and guarantee the integrity of the Standard, several specific restrictions to certification are explicitly provided and regularly updated. Currently, SA8000 certification cannot be applied to Maritime Activities, Fishing Workplaces, and Offshore Workplaces including drilling platforms and oil rigs, mainly because they have working

hours and/or remuneration systems that do not comply with the Standard requirements. Presently, there are no countries where SA8000 certification is restricted, but Myanmar and Pakistan were restricted in the past.

Table 1 presents highlights of the SA8000 certified organizations as at December 31, 2018, showing that more than 4000 facilities in 62 countries are certified, involving two million workers. Even if this seems a rather small number compared to the over one million companies and organizations in over 170 countries certified to ISO 9001 (source: www.iso.org), it should be considered that voluntary social auditing and certification still represent a niche in the business world, even if rapidly growing. Regarding size (Table 2), despite the fact that CSR disclosure is typically pursued by large companies, over 60% of the

certification is with respect to facilities with less than 250 workers. This is probably due to difficulties (and costs) in obtaining and maintaining the certification for companies with a long supply chain, often involving suppliers and subcontractors in developing countries in which complying with the standard could be very challenging. Even if MNEs tend to be relatively exposed to reputational risk, and thus could derive more benefit from certification, they show a low propensity towards adopting SA8000.

In terms of industry trends, 12.1% of certified organizations belong to the textile industry, 11.6% to apparel, 7.6% to construction, 5.9% to cleaning services, 4.1% to food, and 2.8% to metal products, with all other industries presenting much lower percentages. In particular, the first two industries represented (textile and apparel) – which together have more than 20% of the certified organizations – have been exposed to several scandals in recent decades linked to labor exploitation, forced work, and child labor in the supply chains of important MNEs. Here, SA8000 can be seen as a useful tool to limit reputational risk and improve sustainability.

The data regarding the number of SA8000 certified organizations by country (Figure 2) are quite surprising. Consistent with what could be expected given the industry-level percentages, India and China both have a high number of certified organizations (representing the second and third most certified countries, with 28% and 17% of the total number of certified organizations, respectively). These two countries are key areas of delocalization for textile and apparel MNEs companies, which are in search suppliers willing to attain/maintain an ethical outlook (Stigzelius and Mark-Herbert 2009). Thus, being certified as SA8000 can significantly help enhance the chance of local firms being chosen as a supplier by MNEs.

However, the first country by percentage is, perhaps surprisingly, Italy, which is neither a developing country nor has a high number of MNEs delocalizing in developing countries (Heras-Saizarbitoria et al. 2018). Italy's position in this respect is mainly due to the effect of particular regional incentive policies. In particular, in 2001, the Tuscany Region launched the project

“Fabbrica Ethica” (Latin for “ethical factory”) with the aim of promoting a wider spread of CSR in the business world, providing incentives to push firms to gain the SA8000, such as funds to cover the certification costs, 0.5% tax breaks, additional points in public funding calls for tenders, and in public procurement calls for tenders (Del Baldo 2015). The effect of the project has been so impactful that other Italian regions wishing to encourage and strengthen social performance in the workplace issued similar incentives generating a positive imitative effect. This made Italy the world leader for SA8000 certificated organizations – most of which are SMEs with a just national supply chain (Santos et al. 2018) – with an impressive 37.7%. However, the question is if this Standard – originally targeted for developing countries with labor-intensive industries – is

really meaningful for SMEs with a mainly local supply chain located in a country where the national laws are generally much more restrictive than the SA8000 minimum requirements?

Finally, it is notable that no other Western country represents more than 1%: Germany has just 11 certified facilities, France has only 2, the UK and USA have one each. This means that, to date, the Standards completely missed reaching the target of large MNEs.

Benefits and Criticalities of the Standard

The SA8000 offers numerous advantages to the certified firms, first of all in terms of enhancing sustainable supply chain management (Koster et al. 2019; Merli et al. 2015).

Involving the whole supply chain, the Standard can lead to stronger collaboration with suppliers and a deeper knowledge of purchasing processes. The sharing of ethical principles helps to manage the relationship between partners and facilitates both the exchange of information and conflict resolution between buyer and supplier while reducing information asymmetry.

Moreover, fair treatment of workers can enhance engagement, motivation, and productivity of human resources, with a benefit for the effectiveness of the whole firm and its competitiveness (Murmura et al. 2017).

Finally, maybe the most important expected benefits of the certification are on corporate image, and particularly in reducing the risk of being exposed to scandals linked to unethical behaviors. That makes SA8000 an instrument adoptable for protecting reputations (Miles and Munilla 2004). There are two contexts in which the Standard is most effective in improving social performance: developed countries' firms with a global supply chain and developing countries' firms with weak laws in terms of the protection of workers' rights. In most other cases, it can be effectively meaningless, except as a public relations tool.

Besides this criticality, and the anomalous geographical distribution of the certified facilities discussed before, it is possible to highlight at least four others problems, so much so that some authors suggest that the Standard qualifies as an instrument used for greenwashing (see ► [“Greenwashing”](#)), realizing a disconnect between the positive image projected to stakeholders with regard to CSR and companies' actual internal practices in this area (Boiral et al. 2017).

First, the naming itself of the Standard can create ambiguity. The name of SA8000, “Social Accountability,” implicitly suggests that the certification covers all CSR operational aspects, while it is solely focused on workplace conditions and thus could be misunderstood by stakeholders. Even if SA8000 can currently be considered the most important auditable standard in the field of CSR (Sartor et al. 2016), it must be recognized

that it just covers one of the aspects of social responsibility.

Second, the certification bodies presently accredited by SAAS are mainly driven by commercial interests. Although NGOs are eligible to become auditors, currently most of the SA8000 accredited certification bodies are for-profit firms establishing commercial relationships with their clients, which may not be trustworthy. The fact that the auditors are directly paid by the factories being audited undoubtedly raises questions of their independence.

Third, the vagueness of some prescriptions suggests a lack of transparency. A certain indeterminacy on crucial issues like minimum acceptable wages, rights to collective bargaining, and periodic surveillance audit procedures contributes to diminishing the credibility of the Standard.

Fourth, there is still a scarcity of empirical research on the effective outcomes of SA8000 adoption in terms of benefits and (eventual) detriments; thus it is difficult to express a judgment on its value in terms of enhancement of social performance and reinforcement of competitive advantage (Sartor et al. 2016).

Nevertheless, the Standard today still represents one of the most credible assessments of workers' employment conditions.

Summary

SA8000 is a voluntary international standard for auditable third-party verification issued by Social Accountability International (SAI). Today the Standard is the leading worldwide social certification standard for factories and organizations in the field of workers' rights and sustainable workplaces.

SA8000 Standard II

Marek Ćwiklicki

Department of Public Management, Krakow
University of Economics, Cracow, Poland

Synonyms

SA8000:2014; Social management standard

Definition

SA8000[®] Standard is a standard for social responsibility created by Council on Economic Priorities Accreditation Agency in 1997 (CEPAA 1997). Its main focus is on ethical employment and workplace practices. Certification according to this standard assures that a company follows rules referring to the Universal Declaration of Human Rights and International Labour Organization (ILO) conventions and labor laws established at international and national levels (→ Cross Reference: International Labour Standards) (SAI 2014, 2021). The standard's compliance requires a properly designed “management system” which is defined as an operational map (SAI 2021). The management system consists of formal internal regulations covering policies, procedures, and processes. It encompasses actions toward identification and assessment of risks; monitoring, internal involvement, and communication; complaint management and resolution; corrective and preventive actions; and training and capacity building. The management system refers to a team responsible for “social performance” but also to the management of suppliers and contractors, including external verification and stakeholder engagement. The term “social

performance” means full compliance with SA8000 (SAI 2021).

Over the years, the standard has evolved into an overall framework which helps certified organizations to demonstrate their dedication to the fair treatments of workers across industries in various countries. The standard was revised in 2001, 2004, and 2008. The current version is from 2014 (SA8000:2014). Recent documentation on this standard is available on the Social Accountability International’s website (SAI 2019).

Key Dimensions

The standard consists of eight parts (SAI 2021):

1. Child labor: refers to types of work performed by young workers, their hours of work, health and safety, and other risks which could happen during apprenticeship, as well as cooperation with interested parties, including government, local unions, and NGOs.
2. Forced or compulsory labor: refers to restrictions on freedom of movement, financial sanctions (debt bondage), overtime working hours, conditions of cooperation with contractors, and migrant workers.
3. Health and safety: applies to an organization’s actions for creating a safe and healthy workplace environment, ensuring clean and sanitary condition in facilities, and providing protective equipment for personnel and first aid. Apart from material preparation, procedural elements are also necessary, such as risk management, appointment of a senior management representative and “health and safety commitment,” training on risks, and emergency preparedness, procedures, and record-keeping.
4. Freedom of association and right to collective bargaining: includes anti-union discrimination, communication on freedom of association, noninterference in workers’ organizations (e.g., trade unions), or collective bargaining.
5. Discrimination: refers to cultural norms relating to sexual harassment and the treatment of pregnant women, migrant workers or ethnic minorities, workers with disabilities, but also due to age and trade union membership.
6. Disciplinary practices: apply to treating all personnel with dignity and respect.
7. Working hours: include the issue of overtime and work-time averaging. This also addresses fatigue-related accidents.
8. Remuneration: relates to living wage calculation, piecework, and the way how payments to workers are made (e.g., by cash, checks, etc.). It further includes specification toward apprenticeship and casualization of the workforce, covering areas including short-term contracts or homework.

Each part is described similarly in the “SA8000: 2014 Guidance Document” (SAI 2016). The inner structure of each comprises five sections. These include relevant SA8000 definitions, SA8000 requirements, background and intent, implementation guidance, and auditor guidance.

The main points to consider in each particular section are as follows:

- Child labor refers to the obligation not to engage nor support the use of child labor. Child labor is defined in reference to ILO recommendation 146. Action toward this part of standard is defined to include communication policies, employment of young workers under certain circumstances, apprenticeship or on-the-job training programs, and hazards for young workers.
- Forced or compulsory labor also includes human trafficking issues. The organization is required to consider the following issues relating to this subject: freedom of movement, withholding documents, debt bondage, training, resignation letters, and cooperation with trusted employment agencies.
- Health and safety refers to risk assessment or more generally to create a viable risk management system. The organization’s actions in this regard are noted to include identification of potential risks, existence of policies and procedures to deal with the risks, defined management leadership, undertaking actions toward

promoting health and safety, performance monitoring and improvement, and collecting evidence that organizations meet this standard.

- Freedom of association and the right to collective bargaining refers to ensuring the freedom to join a trade union, assuring worker's ability to collective bargaining without discrimination, and noninterference in the worker's intent.
- The organization should undertake actions against discrimination in selection and recruitment procedures. This includes actions to avoid interference in the rights of personnel to observe their beliefs and practices, as well as to prohibit harassment and subjecting workers to various tests, including, for instance, pregnancy, virginity, or other health tests.
- Disciplinary practices should not be enforced as a retaliation against workers and as punishment. A progressive course of action is recommended in favor of nonaggressive discipline methods.
- The working hour management system should include a working hour recording system including regulation for voluntary and non-voluntary overtime.
- Remuneration refers to a wage system which should ensure fairness, providing services for workers at cost prices.

Key Issues

The SA8000 implementations are growing in numbers. The increase is driven by such countries as India, China, Romania, and Brazil which demonstrates how the standard is spreading into large and developing markets. However, the biggest share of issued certifications comes from Italian companies (31%) (Llach et al. 2015).

Studies on implementing the SA8000 standard in developing economies show that the main driver for its implementing is the influence of customer pressure (Koster et al. 2019). The major barrier in the SA8000 implementations is perceived net performance gains.

The standard's construction is similar to other ISO principles referring to quality (ISO 9000) (→ Cross Reference: ISO 9000) or the

environment (ISO 14000) (→ Cross Reference: ISO 14000 standard). The SA8000 is similar to other certified quality or environmental management systems which encourage companies to introduce integrated management system (Santos et al. 2018).

The implementation of SA8000 is perceived as decreasing information asymmetry between management and employees which is claimed to positively impact an organization's performance but not its profitability (Orzes et al. 2017). The research findings demonstrate that socially responsible activities could bring benefits for an organization which are not observed in a company's balance sheet.

Future Directions

Specific knowledge and details on the causal decision-making processes undertaken to certify an organization according to SA8000 and the underlying values and motives are still incomplete (Koster et al. 2019). Moreover, some scholars argue that certification does not mean that internationalization of accountability standards took place but is merely a symbolic gesture to impress stakeholders (Testa et al. 2018).

The future challenge lies in influencing the supply chain to move toward SA8000, as the standard refers only to one focal company (Sartor et al. 2016). However, SA8000 is observed as a key route to improving the supply chain management by bringing together issues related with the standard like health, safety, and environmental management (Chiarini and Vagnoni 2017).

Implementation of the SA8000 compared with the ISO26000 (→ Cross Reference: ISO 26000) produces weaker impact on socially responsible strategic management (Chiarini and Vagnoni 2017). Moreover, none of the mentioned standards indicate a clear influence on financial issues. These aspects prompt questions relating to the noneconomic impacts of the SA8000 on organizational performance, as well as on society.

Furthermore, the resulting challenges in developing this standard constitute required adjustment toward different national cultures, increasing the

dialogue with stakeholders, and adaptation by small companies (Llach et al. 2015).

SAM Sustainability Indices

Belén Díaz Díaz and Rebeca García-Ramos
Department of Business Administration,
University of Cantabria, Santander, Cantabria,
Spain

Synonyms

[ESG index](#); [Social responsibility index](#)

Definition

SAM Sustainability Indices are social responsibility indices that track the stock performance of the world's leading companies in terms of economic, environmental, social, and governance (ESG) criteria. These indices are benchmarks for investors who have recognized that sustainable business practices are critical to generating long-term shareholder value and who wish to reflect their sustainability convictions in their investment portfolios. The indices also provide an effective engagement platform for investors who wish to encourage companies to improve their corporate sustainability practices.

Introduction

Social responsibility indices, like traditional stock market indices, are indicators that track changes in the price of the leading stocks on the stock market, in this case, the social responsibility market. The methodology used for creating an index varies, depending on the institution that designs, manages, and publishes it.

SAM, founded in 1995, is one of the world's first asset management companies focusing on sustainable investing. In 1999, SAM launched the Dow Jones Sustainability Index (DJSI) in partnership with S&P Dow Jones Indices. SAM was renamed RobecoSAM in 2013, and together with S&P Dow Jones Indices, it launched the DJSI Diversified Family.

SAM has developed four sustainability index families: the Dow Jones Sustainability Indices (DJSI); the S&P ESG Index Family; the S&P Fossil Fuel Free Carbon Efficient Index families; and the ESG factor Indices.

Key Issues

The **Dow Jones Sustainability Indices (DJSI)** are a family of best-in-class benchmarks for investors who want to choose socially responsible companies in their portfolios (considering economic, environmental, and social criteria).

The DJSI combine the experience of an established index provider (S&P Dow Jones) with the expertise of a specialist in sustainable investing (SAM) to select the most sustainable companies from across 61 industries.

The DJSI applies a transparent, rules-based component selection process based on the companies' total sustainability scores resulting from the annual SAM Corporate Sustainability Assessment (CSA). Only the top-ranked companies within each industry are selected for inclusion in the Dow Jones Sustainability Index family. No industries are excluded from this process.

The DJSI family comprises global, regional, and country benchmarks: DJSI World; DJSI North America; DJSI Europe; DJSI Asia Pacific; DJSI

Emerging Markets; DJSI Korea; DJSI Australia; DJSI Chile; and DJSI MILA Pacific Alliance.

Every year, DJSI World invites 4,500 of the largest companies listed on the S&P Global BMI, from which 10% of the best-in-class companies in terms of economic, social, and environmental management are chosen from each industry (20% in regional indices and 30% in country indices). The selection is based on a **questionnaire** containing questions about corporate governance, environmental policies, CSR communication, human capital development, philanthropy, health and safety, engagement with stakeholders, etc.

In summary, the aspects to be assessed and included in the index cover economic, environmental, and social factors, such as the following:

Economic

- Code of Conduct
- Corporate governance
- Customer relationship management
- Financial soundness
- Investor relations
- Risk and crisis management
- Measurement systems and dashboards
- Strategic planning

Environmental

- Environmental policies and management
- Environmental performance
- Environmental reporting

Social

- Dialogue with stakeholders
- Human capital development
- Knowledge management
- Employment practice indicators
- Talent attraction and retention
- Supplier standards
- Philanthropic activities
- Social reporting

However, for investors who wish to limit their exposure to controversial activities, RobecoSAM and S&P Dow Jones Indices also offer the DJSI

Indices with exclusion criteria such as armaments and firearms, alcohol, tobacco, gambling, and adult entertainment.

The **S&P ESG Index Family** offers investors exposure to companies according to their ESG profile in the context of country-specific and regional indices (23 S&P ESG Indexes exist in 2019). The index family is based on S&P DJI ESG Scores, calculated by RobecoSAM, and based on the results of the annual SAM Corporate Sustainability Assessment (CSA). The index family includes broad market indices such as the S&P 500 ESG, S&P Europe 350 ESG, S&P Global 1200 ESG, and S&P Japan 500 ESG, designed to closely track their parent indices with a similar risk and return profile.

The S&P ESG Index Family is designed for investors wishing to integrate ESG factors into their core investments while not straying far from the overall profile of S&P broad market indices.

The **S&P Fossil Fuel Free Carbon Efficient Index families** were developed to meet investors' growing demand for low-carbon and fossil fuel-free investment vehicles. They are suitable for investors who wish to hedge against exposure to climate change-related risks, such as the risk of stranded assets, and/or who wish to reduce the carbon footprint of their portfolios and contribute to a transition to a low-carbon economy.

ESG factor Indices combine ESG with other common factors (such as low volatility or dividend yield). They are suitable for investors that want to avoid ESG-related risks in their portfolios by directing their investment toward more sustainable companies without forgetting other common factors in the investment decision.

Competitors

The **Financial Times Stock Exchange 4 Good (FTSE4Good)** was created in 2001 by the FTSE in partnership with Ethical Investment Research and Information Service (EIRIS) and UNICEF. Although it is listed on the London Stock Exchange, it is broken down into a family of indices according to geographic area (e.g., Europe, United Kingdom, United States, Japan, Australia, and Spain).

The index is managed by an independent executive board which oversees the preselection criteria based on recognized CSR standards, which considers 300 indicators on 14 topics related to the three core ESG criteria (environmental, social, and governance).

Environmental

- Climate change
- Water usage
- Biodiversity
- Pollution and resources
- Supply chain

Social

- Health and safety
- Working conditions
- Human rights and community
- Responsibility to clients
- Supply chain

Governance

- Corporate governance
- Risk management
- Fiscal transparency
- Anti-corruption

Businesses excluded include tobacco, weapons, or controversial weapons components (antipersonnel mines, nuclear weapons, chemical or biological weapons, depleted uranium, and cluster munitions).

Future Directions

Investment in companies included on sustainability indices (or socially responsible investment – SRI) have gained vital importance among large investors, as responsible policies in social and environmental matters are viewed as a reflection of good management practice by the organization both externally and internally, helping to minimize risks and prevent crises, thereby avoiding slumps in

their stock prices, and protecting shareholders.

Analysts agree that indices such as the DJSI and the FTSE4Good provide reliable verification of companies' economic social and environmental performance. Given the difficulty and stiff competition among firms to enter these indices, being listed by them conveys a positive image of solvency, which is valued by anyone looking to invest in or to do business with these companies.

For listed companies, belonging to an internationally recognized sustainability index, implies an acknowledgement of their CSR policies and enhances their reputation, helping them to secure sources of funding.

In principle, SRI performs as well as conventional investment, meaning it is possible to choose responsible companies without having to pay more. Numerous empirical studies conducted in the United States and Europe reveal that there is no significant difference between the performance of SRI and conventional investments. In nominal terms, the profitability of SRI is usually higher than that of conventional investment, but taking account the investment risk, this difference is offset, because SRI often has a higher risk (volatility) index. This conclusion was obtained by Bauer, Koedijk, and Otten (2005) among others, after analyzing data from three countries: Germany, the United Kingdom, and the United States.

Summary

Sustainability Indices are social responsibility indices that track the stock performance of the world's leading companies in terms of economic, environmental, social and governance criteria (ESG). This chapter describes SAM Sustainability Indices, their main competitors and future directions for Socially Responsible Investment (SRI).

Sanctions of Social Capital

Nguyen Hoang Nam

Department of Economics, Politics and Society,
University of Urbino Carlo Bo, Urbino, Italy

Synonyms

[Behavioral incentives](#); [Conformity](#); [Consequences of social capital](#); [Norm enforcement](#); [Social control](#)

Definitions and Description

The three fundamental components that can be observed in most forms of social capital include: a network, a cluster of norms, values and expectations that are shared by group members, and sanctions/punishments and rewards, which help maintain the norms and networks (Halpern 2001). In a society with strong norms, transparent and effective sanctions can reduce criminal action incentives, and those who are not fearful but feel secure in their environment have better chances to develop stronger ties within their community. Woolcock and Narayan (2000) define effective norms as ones that can encourage transactions, lower transaction costs, minimize information costs, enable exchanges in the absence of written contracts, promote accountable citizens, and improve collective resource management. Coleman (1990) claimed that norms are generated to cope with the potential costs of externalities,

that is, in situations when an action has a negative (positive) impact on other parties, without being reflected in direct compensation; thus the producer of externality pays no costs (obtains no benefits) for the unintended impact of their activity. A norm addresses the issue by controlling the externality-generating behavior, and thereby introducing sanctions (rewards).

Essentially all three components of social capital (networks, norms, and sanctions) possess two principal aspects: formal – explicitly and institutionally codified – and informal – implicit and tactical. A large portion of sanctions are informal, nonetheless they are effective in maintaining social norms (Luzzati 2000). For instance, life in a neighborhood is often associated with certain kinds of informal sanctions, although it might be of a mild form but still very effective, for good and bad behaviors. Neighbors find ways to express resentment to social conduct that breaches the neighborhood's unwritten rules. Quite often, their sanction is indirect and implicit, such as through gossiping or other mild forms of reputation damaging.

A social network sets its standards by sanctioning individuals who break its norms and rewarding people who adhere to them. This particular set of sanctions and the informal, often unwritten norms are reflections of social capital. A network with strong social capital is a network with strong ties, shared values, effective communication, and is capable of supervising its norms. Very commonly, the most successful sanction is to sever from the community the social ties of an individual who breaches norms. If value lies in connections within and beyond networks, and social capital is an asset that can be obtained through those connections, then the dissolution of connections can deny someone their social value and capacity of value-generation. An example is when a monarch would banish someone from court, or from the country, as a punishment. This banishment does not simply mean a loss of contacts and wealth; it also means removing the power and capacity of that individual to create value from a social network, by denying them of their impact, reputation, or ability to grant favors. This form of sanction requires a dynamic social

network in which connections are created and dissolved quite rapidly. In such a dynamic social network, dissolving or forming social ties can be used as a sanction or reward. In a large, dynamic network, cooperators are quickly pulled into the network through tie formation, and non-cooperators are pushed out through tie dissolution. This mechanism also causes activities within a dynamic network to be amplified. If people who conform to a norm, like reciprocity, are rewarded with new connections, then the network attracts cooperative people and becomes more cooperative as a result. In contrast, for a stagnant network with few new people entering or moving through the network, reciprocity is mostly monitored by whether or not it is returned. Non-cooperators will be forced out of a dynamic social network and would struggle to join another network precisely because of this mechanism; reciprocity becomes a selective attribute. A social network with strong internal ties and multiple weak bridging ties is rich in social capital.

There are a number of typologies of sanctions. Sanctions can be identified as formal or informal: formal sanctions are imposed through formal means by an institution/organization, often documented in policy, rules or regulations, and can include fines or rewards for deviation or compliance; informal sanctions are imposed by individuals or groups without the use of a formal system, such as shaming, boycotts, gossiping, etc. Another distinction between different types of sanctions is between internal and external sanctions. Internal sanctions are consequences imposed by the individual herself, based upon compliance with social norms. For example, an individual might suffer from embarrassment, shame, or depression as a result of non-compliance and associated exclusion from social groups. External sanctions, on the other hand, are consequences imposed by others such as expulsion from a group, public humiliation, punishment by management, arrest and imprisonment, etc. Sanctions can also be defined as positive or negative: actions that meet normative expectations or conform to norms are subject to a positive sanction; failure to meet such expectations leads to punishment – also known as

negative sanction. Sanctions do not always have to be activated to be effective, as their mere threat or possibility of a sanction can influence behavior.

Posner and Rasmusen (1999) analyzed in detail the variety of sanctions that can enforce norms, as well as the degree of enforcement associated with each type of sanction. They divided sanctions into six types: automatic sanctions, guilt, shame, informational sanctions, bilateral costly sanctions, and multilateral costly sanctions. A norm can be enforced by more than one sanction. The violator's action carries its own penalty in *automatic sanction*. Norms also impose themselves in the sense that the violator is immediately punished without anybody's deliberate interference. But the punishment may not be sufficient, as the violator only recognizes the cost to himself and not to others. In the case of *guilt*, as a result of his education and upbringing, the violator feels guilty about his infringement. Guilt is an internal punishment, and thus does not depend on information being disseminated. It could be thought of as a type of automatic sanction, as it is perceived by the violator as a cost to himself, however differs from a simple automatic sanction in requiring expenditure to create. A level of effort must be made to instill the potential for feeling guilt, as well as the amount of guilt to instill. The sense of guilt may be innate, but it is also established by formal education, purposeful moral control by parents and relatives, and the examples offered by both adults and peers. As with *shame*, the violator feels that his action has lowered his value either in his own eyes or from the view of other people. In its most usual form, shame emerges when other people find out about the violation and think badly of the violator. The violator may also feel ashamed even if others do not discover the violation, knowing what they would think if they did discover it, a moral sentiment which can operate almost automatically. Shame is often a byproduct of bilateral or multilateral sanctions. When people criticize a norm violator they are trying to impose a multilateral sanction, but the uselessness of the criticisms to the violator, and thus the efficacy of the sanction, may be due entirely to shame. Shame, like guilt, is a product, in part at least, of both formal and

informal education. It is worth noting that since the attention is on the violator's status rather than on the violation, there can be shame even if there is no breach of a moral code: one can be ashamed simply of doing something stupid that is harmful to nobody, as behaving stupidly is considered failing to live up to their own self-image. Humiliation is considered as a form of shame, while shame itself is a purely external sanction for violations of the moral code. As an external sanction, shame can be felt even if other people take no action.

In case of *informational sanctions*, the act of violation conveys information about the violator that he would rather others not know, for example, a student wears casual clothing to a job interview, unintentionally signaling his lack of interest in getting the position. The sanction not only imposes severe costs on the violator, but its cost to the enforcer of sanction is actually negative, because he has removed a potential loss by avoiding dealings with this person who by his violation has revealed himself to be an unreliable transactional partner. The personal characteristic revealed by the violation, not necessarily directly related to the violation that has been made, yet still can convey valuable information. For *bilateral costly sanctions*, the violator is punished by the actions of and at the expense of just one other person, whose identity is revealed by the norm. The expense to the enforcer could be the effort needed to cause the violator disutility, or the utility that the enforcer imposing the sanction loses by punishing the violator. These require only a minimal dissemination of information; the designated punisher is the only person who needs to learn of the violation. The difficulty lies in getting the punisher to carry out the punishment, given that it is costly to him, which as mentioned earlier may require a more complex sanctioning system involving second-order internal norms, or facilitating punishment by reducing its costs. Finally, with *multilateral costly sanctions*, the violator is punished by the actions and at the expense of many other people involved. Multilateral punishments require more information than bilateral ones. The free-rider problem is exacerbated because more people are involved in executing

the sanction but ameliorated because each punisher's cost of punishment can be less for the same total deterrent.

All six sanctions have analogies in terms of rewards for obedience to norms. A reward may take the form of a feeling of a well-done job, material appreciation from one or more people, automatic benefit from coordinated interaction with another, the signaling of desirable qualities, or other people's good opinions.

Effective sanctions rest critically on the foundation of shared norms and network structure (Coleman 1988). Norms influence behavior because they become part of one's motives for action through a socialization process that begins in infancy. Compliance with standing norms is a stable, acquired disposition, irrespective of the consequences of conformity. Long-term interactions with significant others usually form such lasting dispositions, via repeated socialization, individuals learn and internalize the common values embodied in the norms. Internalization is defined as the mechanism through which people develop a psychological need or motivation for conformity with a set of shared norms. Once norms are internalized, norm-abiding conduct will be viewed as positive or acceptable, and people will usually feel guilt or shame at the possibility of a deviant behavior. When internalization is successful, external punishments will not necessarily play a role in achieving conformity and it follows that normative beliefs and actions will be consistent because individuals are compelled to conform.

Early rational choice models of conformity maintained that, because norms are often imposed by sanctions, conformity is simply considered a payoff-maximizing strategy (Rommetsveit 1955). Others' approval and disapproval act as external sanctions in a "cost-benefit model" of compliance (Axelrod 1986; Coleman 1990). To avoid negative sanctions or to attract positive sanctions, rule-complying strategies can be rationally formed. This class of rational choice models explains norms behaviorally, attributing them to behavioral patterns while ignoring expectations or values, relying heavily on sanctions as a motivating factor. Along this line, Axelrod (1986) showed the

creation of norms taking place when individuals follow a regular pattern of behavior and are punished if they act otherwise. Coleman (1990) argued similarly that a norm corresponds with a series of sanctions that serve to guide a particular behavior.

It has been shown that not all social norms involve sanctions (Hoebel 1954). Moreover, sanctioning usually functions effectively in smaller groups and in the context of repeated interactions, with known identity of participants and simple monitoring. Still, even in such cases there may be a so-called "second-order" public goods problem. That is, imposing negative sanctions on violators is in everybody's interest, but the individual who observes a violation has to decide on whether or not to punish the violator as sanction typically involves costs, and there is no guarantee that others will similarly impose a sanction when witnessing the same violation. A possible solution to this dilemma is the existence of "meta-norms" that direct the punishment of violation of lower-level norms (Axelrod 1986). It is worth noting, however, that upholding the meta-norms requires the presence of a more complex sanctioning system.

Norms are not only upheld by external sanctions. Even in cases of complete anonymity, where the risk of being found violating is almost zero, many people still tend to adhere to norms; fear of sanctions is simply not a motivating force in this case. As a result, Scott (1971) argued that cases of "spontaneous" compliance result from internalization; people who have developed an internal sanctioning system feel guilty and shameful about behavior in a deviant manner. Nevertheless, this does not mean that external sanctions never play a role in compliance: it may indeed play an important role, for example, in the initial development of a sanction. There are several mechanisms that can account for conformity once a standard is already formed.

Community norms are partially established through the existence of sanctions (Posner and Rasmusen 1999). A sanction should be of the correct magnitude; citizens will be over deterred if it is too harsh and avoid making effective actions. Similarly, a sanction should not be too

costly; the expense would largely depend on how often it has to be imposed, that is, on the frequency of the norm's infringement. Due to the informality of compliance, it is necessary that the application of a sanction not require too much information. Punishment would not exist at all if it will not be effective unless many people learn about the violation.

Norms are particularly effective devices for social control, relative to law, when individual violations are simply minor, or the difficulty of proving guilt is too great, to justify the expense of courts, police, and prisons. But the sanctions for violating norms are often too weak to dissuade all people from many offenses, while the creation of norms is too slow to provide for all the rules necessary for society's governance – therefore the laws also need to have their place. If the informal penalty for breaching a requirement is insufficient, the government can provide additional punishment via laws and regulations. Nonetheless, it is a common observation that norms are more important to the prevention of minor crime than laws although one may wonder whether the norms could long survive the absence of laws. The case of commercial norms which emerged before being imposed by courts is an example of a possible scenario. The government can often leave to the private sector the promulgation of a desired norm while offering penalties for violations once the norm has been created. Legal sanctions for violating norms are also relevant due to the fact that many individuals are impervious to informal sanctions. They lack guilt and shame, or worry for ostracism because they do not have any valuable transactional opportunities, or a reputation to risk; but they are still vulnerable to the law's tangible sanctions.

Summary/Conclusion

Network, norms, and sanctions/rewards are the three fundamental components of social capital, within which sanctions/rewards play the important role of maintaining the norms and networks. There are a number of typologies of sanctions: it can be identified as formal or informal, internal and

external, or taxonomized based on the degree of enforcement (such as automatic sanctions, guilt, shame, informational sanctions, bilateral costly sanctions, and multilateral costly sanctions). A social network establishes its shared norms and values by sanctioning individuals who violate them and rewarding people who adhere to them. A network with strong social capital is a network with strong ties, shared values, effective communication and is capable of supervising its norms, partially through the use of sanctions. A sanction should be of the correct magnitude; citizens will be over deterred if it is too severe and avoid making effective actions.

Sarbanes-Oxley and Nonfinancial Reporting

Corporate responsibility

Definition

The Sarbanes-Oxley Act (Public Accounting Reform of Investor Protection Act), commonly known as SOA or SOX, has been introduced in 2002 and it represents one of the main rules about financial reporting, corporate governance, and accountability for companies listed on NYSE. The SOX has been introduced in order to favor the achievement of the highest level of investors' trust about financial markets. In fact, it followed a period characterized for several financial scandals and irresponsible behaviors from managers. In this sense, one of the main aims of SOX was to favor the introduction of more ethical behaviors by managers.

Despite the absence of specific requirement about nonfinancial disclosure, the SOX impacts on nonfinancial information provided in traditional annual reports. Specifically, SOX has broadened the scope of accounting report to the sustainability programs provided into the strategic planning of the companies.

The SOX: A Brief History

The SOX represents the most relevant reform about financial markets after the introduction of Security Exchange Act in 1934. The introduction of the SOX followed a period characterized from several corporate scandals caused by the ineffectiveness of external and internal control on companies' activity.

One of the main phenomena related to the introduction of SOX was the Enron's bankruptcy (Burrowes et al. 2004). The financial scandal was unexpected for investors due the existence of managers' manipulation on financial data in order to increase the market value of Enron (Petrick and Scherer 2003). The bankruptcy effect was disruptive for the entire economy due the negative effects on investors' financial resources.

According to this evidence, in 2002, the US context was characterized by a high level of distrust about financial markets. In this sense, SOX impacted on managers' behaviors. In fact, as evidenced in prior studies, large part of companies' bankruptcy has been connected to abuse of position from external managers. Specifically, prior studies suggest how in that period large part of the firms was characterized from lack of control of shareholders about managers' behaviors. In order to fill this gap, the main idea behind the introduction of SOX was to redefine companies' internal organization to new operational paradigms (Sisaye 2015).

From "Corporate Responsibility" to "Corporate Social Responsibility"

Although the main aim of SOX is to preserve investors from financial frauds, the SOX impacts indirectly on nonfinancial disclosure (Ryznar and Woody 2014). This relationship is related to the SOX's provisions of an explicit connection to the concept of "corporate responsibility." Specifically, the Title III of SOX who is called "corporate responsibility" consists of a set of provisions about the contents of the traditional annual reports and financial report provided by the firms. Furthermore, Title 3 analyzes the role covered from managers, directors, and auditors in terms of code of conduct.

Nowadays, the increasing number of nonfinancial information provided by listed firms imposed for US firms to consider them in their strategies in order to be compliant with SOX. In fact, an increasing number of US firms has started to disclose nonfinancial information into their traditional communication tools (KPMG 2017) and

an increasing number of investors have started to consider the “socially responsible investment” in their financial strategies (Sparkes 2017). Furthermore, similarly to financial fraud, the recent non-financial scandals have shown how the disclosure of false nonfinancial information impacts negatively on financial markets (Du 2015).

Several studies have tried to evaluate the SOX’s effect on nonfinancial disclosure. Specifically, these studies reveal how SOX indirectly represent a way to reduce the risks of unethical behaviors of managers in nonfinancial reporting. In fact, as evidenced before, a large part of literature has shown how the absence of a set of common rules impact positively on the risks of managers unethical behaviors. Specifically, these studies highlight the existence of nonfinancial disclosure based on impression management strategies or characterized by greenwashing (Siano et al. 2017). Furthermore, empirical studies based on the US context reveal that firms interested by financial scandals adopt socially responsible practices in order to mitigate the negative effects connected to their hypocrisy (Janney and Gove 2011).

However, the comprehension of the interlinkage between SOX and nonfinancial reporting represents a complex activity. In fact, despite the theoretical implications related to internal auditors’ involvement in nonfinancial reporting practices, only few insights were collected by academics. Within this debate, the European context could represent an interesting setting due to the cross-listing’s phenomenon. In fact, European PIEs interested by Directive 2014/95/EU that operate overseas and are listed in the US market are influenced by the SOX (Litvak 2007). Furthermore, a large number of US organizations started to revise their paradigms in order to actively contribute to the sustainable development (World Economic Forum 2020). In this sense, building on the prior evidences about IFRS, the next years will be useful to understand in which way mandatory internal control systems can influence the quality of nonfinancial reporting practices.

Summary

The achievement of stakeholders’ trust represents one of the main goals for listed firms. Nowadays, the recent scenario has been characterized for several financial scandals that have impacted negatively on stakeholders’ perception about financial markets. Moreover, an increasing number of firms have started to disclose false information about their nonfinancial impacts in order to increase their legitimacy. Furthermore, in context characterized by absence of a set of common rules about nonfinancial reporting, the use of greenwashing and the abuse of impression management strategies represent two criticisms for an effective stakeholder engagement. According to this evidence, financial markets need tool able to mitigate directly or indirectly these risks. In this sense, the SOX represents an interesting tool to mitigate these risks through the provisions of a set of common rules about managers and auditors’ behaviors. However, the increasing number of nonfinancial information disclosed by listed firms on their reports and websites will increase the necessity to update the content of SOX to the new investors’ exigence.

Selling Cycle for Sustainability

Chahid E. Fourali

London Metropolitan University, London, UK

Synonyms

[Selling steps](#); [The selling cycle](#)

Definition

In 2007, the Marketing and Sales Standards Setting Body (MSSSB) (see Rogers [2007](#)), the then UK national body, representing the sales profession (in addition to the marketing profession) stated that the Key Purpose of selling is:

To create, build and sustain mutually beneficial and profitable relationships through personal and organisational contact (Rogers [2007](#), quoting MSSSB, page XIX).

This is clearly beyond the simple here and now transaction that is generally understood by “selling.” A professional salesperson was expected to have competencies that involve knowing the target market, planning an effective sale, financing the sale, leading sales teams, communicating effectively, creating sales opportunities, implementing the sales cycle, supporting sales, and managing customer relationships.

Selling can apply to various situations including

- Direct selling, or face to face contact with the customer
- Retail selling, where products are offered through a shop
- Agency selling, when products and services are offered on behalf of a supplier
- Telesales, where products and services are sold directly on the telephone
- Door to door selling, which involves visiting potential customers in their homes
- B2B, businesses sell directly to other businesses

- Business to government selling, businesses develop solutions offered to government agencies and departments
- Mail order selling, when customers buy from a catalogue
- Online selling, or selling via the Internet

Introduction

Selling has, in the opinion of many, a very bad reputation as a profession, due to the unscrupulous behavior of the few, probably encouraged by an irresponsible corporate culture that may be focused on short sighted “here and now gain at any price.” Nevertheless, it has also been called the lifeblood of business. This is understandable since no company can survive if it cannot sell its products or services, either to its customers, or stakeholders (including owners, employees, authorities, local community, etc.).

Selling per se is usually reflected on the concept of sales cycle. This contains the steps that every organized sale’s person goes through. We will describe the seven steps that make up this cycle.

It starts with what has come to be known as the sales preparation stage. In this stage, the sales person identifies sales prospects, carries out the background research about the company, and determines a plan for selling to it. This is followed by the second stage, or introduction to client stage, when sales’ people introduce themselves to the client and try to set up a meeting with the targeted representative of the company. Stage 3 starts straight after the introduction but extends to subsequent meetings/communications when the sale’s person investigates the needs of the company and develops the relationship with the representative. In stage 4, the sales person gives the sale’s presentation, which would have benefited from all the previous stages. In stage 5, the sale’s person invites any feedback and objections from audiences and addresses them systematically based on the advantages the client derives from the product or service. In this stage, some “give and take” negotiations take place with a view to reach a mutually satisfactory outcome. Stage 6 is

reached when a deal has been closed. This signals the beginning of the formal relationship and the sales person is aware that honoring promises and looking after the new client is the best way to keep the relationship going.

Key Issues

As stated above, selling may not have had a very good reputation because of the unethical practice of unscrupulous sellers. However, no business can survive without selling its commodities. This brings up the question: how can professional selling be made more trustworthy? Clearly any activity can be carried out ethically or unethically and perhaps sales training should take into account underpinning values before recruiting their sales workforce. The golden rule (thou shall treat others as you wish to be treated) appears to be a contender for a foundation of ethical behavior. Hence, it is popular among business authors. Once a value foundation has been agreed, businesses need to review sources of claim of unethical behavior and integrate the learning within their salesforce training programs. If the golden rule is accepted by sales people, then they would be more willing to adopt the tricomponent model of doing business (i.e., not only focusing on making a profit but also demonstrating social and environmental responsibilities).

Once the tricomponent model of doing business is accepted, then it is important to systematically highlight the various areas where irresponsible practice may occur. A systematic way of reviewing sources of irresponsible behavior is to refer to the above sales cycle stages and identify potential problems.

For example, in stage one, the preparation stage, where the sales person identifies sales prospects, carries out the background research about the company, and determines a plan for selling to it, the responsible sales person would genuinely look if there is a need for the products being sold. He should aim to find out as much as possible about the company and how the product would benefit it: more sales, more profits, more care for

its employees, environment protection, and subsequent reputation etc.

In the second stage, the introduction of the salesman stage, the responsible salesperson will aim to be as transparent as possible about their identity, aims, and objectives.

In the third stage, or fact-finding stage, the responsible salesperson avoids adopting leading questions or misusing information given in confidence.

In the fourth, presentation stage, the salesperson should ensure that all statements or claims are true.

In the fifth, dealing with objections stage, it is important that all relevant information is provided so the client makes a decision in view of all the facts.

In the sixth, closing the deal stage, the salesperson should avoid putting any pressure on the clients and rush them into a decision that they may regret later. It is also expected that other clients in similar conditions should receive a similar deal.

Once the sale has been completed (seventh stage), it is expected that the salesperson honors all their promises, including the after-sell ones.

Finally, it is worth remembering that at times the targeted company's needs may not be as expected. In such cases, the salesperson should explain that the product may not be appropriate and, if possible, offers some alternative advice.

Future Directions

Selling is a very demanding responsibility especially as it involves a plethora of skills including selling theory, communication skills, human psychology, emotional strength, knowledge of the industry associated with the product among others. For the global companies that deal with an international clientele, there is also the need to understand local languages in addition to appreciating cultural differences, which are also colored by local politics. Although most people would sympathize with sustainability arguments, it is clear that such arguments may be located at a lower level of either company culture or economic

geographical areas. Given that disadvantaged communities may put price at the top of their concern and may miss out issue of social or environmental concerns, it seems to make sense to encourage global companies to integrate social and environmental issues as part of the design of any offer so that whatever option faces a customer there is always no threat to social or environmental issues.

The digital revolution presents both advantages and disadvantages to selling. Among the advantages are the opportunities for resourcing of prospects and relevant information about needs and speedier communications. Among the disadvantages are the easy access to all sorts of products including some that may be detrimental to social and environmental dimensions.

Perhaps it is worth noting that selling should be part of a larger marketing strategy. Indeed, if there is irresponsible selling, this may simply suggest a lack of effective marketing strategy. Marketing is about focusing on the needs of customers and offering something that adds value to the available options for meeting customers' needs. A possible problem is that a sales person focuses on the product they are selling as opposed to the marketer who focuses on addressing needs. However, if the company systematically targeted relevant groups that would benefit from their product then the sales function should be compatible with the marketing philosophy. Adversely, if selling is unethical (e.g., aggressive or irresponsible selling), then this may reflect the culture of the company irrespective of official documents.

[Enactment](#); [Meaning-making](#); [Sensemaking](#)

Summary

Sensemaking is an interdisciplinary concept drawing upon traditions of sociology, philosophy, social psychology, and organizational studies. The theory of sensemaking was developed to explain the way in which organizations create their worldviews. Sensemaking in organizations

is the process by which they make sense of their environments through a process of intervention. Organizations impose their scripts and frames on the flux of their context in order to create their environments through a process known as enactment. Conceptually sensemaking is a postmodernist approach developed to analyze and explain the process by which organizations create, apply, and maintain meaning to equivocal events and information they encounter in order to create an understanding of their environments. This entry will present a brief overview of the concept and characteristic sensemaking as developed by Karl Weick and review their implications for organization.

Introduction: Defining Sensemaking in Organizations

The concept of sensemaking when defined as the process whereby individuals and organizations give meaning to their experience of reality has a long tradition in the social sciences. Aspects of the sensemaking process have been studied and conceptualized by a number of early scholars including James in psychology (James 1890) who examined the relationship between cognition and self-consciousness and their role in objectifying reality and Dewey in philosophy (Dewey 1922) who analyzed the effect of accumulated stresses that spark reconstruction of social habit.

The key concepts of sensemaking have been developed in the work of a number of scholars including Goffman who posed the concept of frames and the process of framing as the mechanism whereby social reality is defined and acted upon by individuals (Goffman 1974). According to Maitlis and Christianson (Maitlis and Christianson 2014, p. 60), sensemaking was first comprehensively conceptually developed in the 1960s through the work of Garfinkel (Garfinkel 1967) and Weick (Weick 1979). It is Weick however who is widely credited with having first examined the implications of the concept of sensemaking for the process of organization and the management of organizations.

According to Weick organizations operate in dynamically changing, complex environments characterized as being in a state of flux (Weick 2011). In order to make this ongoing flow of information and stimuli manageable, organizations attribute significance to some features of their environment by emphasizing particular parts – either information or events – of the flow of experience. Combined, these parts yield an interpretation of their environment upon which organizations base their perceptions and expectations of changing events.

According to Maitlis and Christianson: “Sensemaking is the process through which people work to understand issues or events that are novel, ambiguous, confusing, or in some other way violate expectations” (Maitlis and Christianson 2014, p. 57). Sensemaking is the process that occurs when actors seek to reconstruct their understanding of their environments after experiencing an event that challenges their assumptions regarding the alignment between their environmental perceptions and expectations (Weick et al. 2005, p. 414). Karl Weick, a social psychologist whose theories have greatly influenced the conceptualization of sensemaking, has proposed enactment theory (Daft and Weick 1984; Weick 1969) to explain sensemaking as a four-stage process of organization consisting of (1) change, (2) enactment, (3) selection, and (4) retention (Weick et al. 2005, p. 414).

Change

Organizations constantly encounter change. Unlike ongoing change, the change indicated as the first stage in the sensemaking process is that which occurs when an organization encounters an issue, event, or situation that serves as a “trigger” or a “cue” for sensemaking (Maitlis and Christianson 2014, p. 70). A cue or triggering event is defined by its equivocality. As explained by Kudesia: “Ambiguity and equivocality differ in one important regard. Ambiguity implies that there is some ‘true’ state of the environment out there to be discovered. Equivocality suggests instead that the state of the environment must be invented: by focusing on certain pieces of information and acting on the basis of certain interpretations of that information,

organizations help invent their environments” (Kudesia 2017, p. 9).

The distinction between equivocality and ambiguity is important. Whereas ambiguity can be managed by collecting more information to reveal what is true, collecting more information can actually increase the difficulty of dealing with equivocality and require a counterintuitive process whereby the meanings of events and information are instead reduced (Weick 1979). Encountering an equivocal event therefore requires that the organization attempt to make sense of it (Drazin et al. 1999) – hence the use of the word sense in sensemaking. Sensemaking becomes a conscious process when the experience of events does not meet expectations (Weick 2001). Maitlis and Christianson have identified three types of sensemaking-triggering events: (1) environmental or organizational crisis, (2) threats to organizational identity, and (3) consciously planned intervention (Maitlis and Christianson 2014, pp. 71–76). Earlier studies have primarily analyzed sensemaking as triggered by crisis events (Meyer 1982; Milliken 1990). More recently studies of sensemaking triggered by (1) identity crisis wherein the self-consistency of an organization’s identity is felt to be challenged (Maitlis and Christianson 2014, p. 73) and (2) planned change which results either accidentally or intentionally in the understanding of an organization have been reported.

Enactment

For Weick organizations are “social structures that combine the generic subjectivity of interlocking routines, the intersubjectivity of mutually reinforcing interpretations, and the movement back and forth between these two forms by means of continuous communication. Tensions between the innovation of intersubjectivity and the control of generic subjectivity animate the movement and communication. The goal of organizations, viewed as sensemaking systems, is to create and identify events that recur to stabilize their environments and make them more predictable. A sensible event is one that resembles something that has happened before” (Weick 1995, p. 170). Organizations therefore make sense of their environments by perceiving them in a way that aligns and reinforces their understanding of them

and thus enables the prediction and expectation of future events.

Sensemaking is the process that takes place when this alignment between expectation and prediction is disrupted. Disruption leads to a process of enactment. Enactment as defined by Weick is the way in which organizations “construct, rearrange, single out, and demolish many of the ‘objective’ features of their surroundings... unrandomize variables, insert vestiges or orderliness, and literally create their own restraints as a product of their perception of events and information” (Weick 1979, p. 164).

Weick stresses the difference between enactment and reaction. This perception within Weick’s conceptualization of sensemaking can best be understood as an active and selective process whereby organizations build an “enacted environment” from events and information (Weick 1988, 1993) and not as a simple, passive reaction to changes.

Enactment involves a process of selective attention known as the bracketing of information. Organizations identify equivocal events that confound their expectations and single them out for interpretation. These bracketed instances of events or information represent gaps between perception and expectation and indicate some degree of breakdown in the organization’s worldview and lead to efforts to reduce uncertainty (Ashforth and Fried 1988; Kiesler and Sproull 1982).

Selection

Noticing and bracketing information mark the beginning of sensemaking. Once equivocal information is identified, it is subjected to selection – reduced in volume and organized into a coherent story in order to generate what Weick terms a “locally plausible story” (Weick et al. 2005, p. 414). Selection is a process of interpretation wherein the possible meanings of bracketed information are reduced in order to make it actionable.

Far from being a process of clinical objectivity, selection is influenced by the generic subjectivity of the organization as indicated by Weick, as well as by relationships of power as noted by Ocasio. For Ocasio, selection is “both a cognitive process and a political process as organizational members

struggle with the definition of the situation and the resulting choices consistent with the definition” (Ocasio 2000, p. 51).

Weick, Sutcliffe, and Obstfeld explain that: “noticing and bracketing, triggered by discrepancies and equivocality in ongoing projects, *begin* to change the flux of circumstances into the orderliness of situations” [italics original] (Weick et al. 2005, p. 414). Selection reduces possible interpretations which are then consolidated in the following stage of retention.

Retention

Retention is the process whereby plausible interpretations are identified and retained. For Weick, plausible interpretations are those which make sense in terms of their being: “related to past experience, connected to significant identities, and used as a source of guidance for further action and interpretation” (Weick et al. 2005, p. 414). Retained stories become part of the organizations identity and then serve as an understanding that frames the ongoing process of enactment by serving as “a sensible rendering of previous events stored in the form of casual assertions, and made binding on some current enactment and/or selection” (Weick 1979, p. 166).

Phenomena similar to the concept of the interpretations that emerge from Weick’s retention process have been identified by other scholars. These include Lord and Roti (1986) who define schemas by which organizations act to bring structure to experience, Gioia who describes cognitive maps as “scripts” that act as a “default mode of organizational cognition” (Gioia 1992, p. 386), and both Goffman (Goffman 1974) and Schein (Schein 1992) who employ the concept of a “frame” in a similar manner.

Weick’s Characteristics of Sensemaking

Weick has defined seven characteristics of sensemaking that both define it and distinguish it from “understanding, interpretation and attribution” – specifically its being: “(1) grounded in identity construction, (2) retrospective, (3) enactive of sensible environments, (4) social, (5) ongoing, (6) focused on and by exacted cues, and (7) driven

by plausibility rather than accuracy” (Weick 1995, p. 17).

The process of sensemaking is linked to identity in that organizations create the reality of their environments by interacting with it in a way which is meaningful in terms of their own subjectivity. Organizations project their own identities onto their environments and “observe the consequences” (Weick 1995, p. 23). Identity defines action, and the consequences of these actions in turn shape identity.

Weick has observed that retrospection is perhaps the key distinguishing characteristic of sensemaking as a process (Weick 1995, p. 24). Sensemaking is triggered by the experience of the unexpected. As such it starts with the interpretation of what has occurred and concludes when a suitable explanation has been found. Choo has identified this retrospective imposition of meaning under the enacting organization model of sensemaking and contrasted it against the forward-looking nature of meaning creation assumed under rational organization models of decision-making and the scaled knowledge creating models of systems theory (Choo 2006).

Weick uses the example of legislators and managers to illustrate the process by which organizations enact their environment. For Weick: “when people enact laws they take undefined space, time, and action and draw lines, establish categories and coin labels that create new features of the environment that did not exist before” (Weick 1995, p. 31). By making sense of an environment, organizations give it meaning through the act of interpretation. Sensemaking is a result of action.

The social nature of sensemaking lies in the fact that stories and narratives that define enacted environments are shared. For Weick “sensemaking is never solitary because what a person does internally is contingent on others. Even monologues and one-way communication presumes an audience. And the monologue changes as the audience changes” (Weick 1995, p. 40). Rather than seeing sensemaking as a process of creating a shared understanding of reality, Weick’s emphasis is on the negotiated nature of the process involved and the existence of what are termed “cues for

coordination” including stereotypes and roles (Weick 1995, p. 42).

Sensemaking is cyclical and ongoing. As Weick explains: “sensemaking never starts. The reason is that it never starts is that pure duration never stops. People are always in the middle of things, which become things, only when those same people focus on the past from some point beyond it. Flows are the constants of sensemaking. . .” (Weick 1995, p. 43). Sensemaking is an ongoing process because it involves the dual goals of making sense of that which has occurred at the same time as creating order out of the flux (Weick 1993, p. 635).

Sensemaking is based upon the analysis and interpretation of extracted cues. According to Weick: “extracted cues are simple, familiar structures that are seeds from which people develop a larger sense of what may be occurring” (Weick 1995, p. 50). The context influences both what cues are extracted and how they are interpreted. This is due to sensemaking representing an intersubjective as opposed to an objective process and as an act of interpretation and not a process of clinical observation or “noticing” (Weick 1995, p. 51).

The last characteristic – one closely aligned with the previous characteristic of interpretation – is that sensemaking aims for “plausibility, coherence, and reasonableness” (Weick 1995, p. 61) not accuracy in proposing an acceptable understanding of equivocal experiences. Weick elaborates on this by observing that “it would be nice if these acceptable accounts were also accurate. But in an equivocal, postmodern world, infused with the politics of interpretation and conflicting interests and inhabited by people with multiple shifting identities, an obsession with accuracy seems fruitless, and not of much practical help. . .” (Weick 1995, p. 61).

Sensemaking and Organization

Sensemaking is a part of the postmodernist tradition. As defined by Powell, Lovallo, and Fox, the field of behavioral strategy aims to merge “cognitive and social psychology with strategic management theory and practice,” thereby “grounding strategic management in realistic assumptions about human cognition, emotion, and social

interaction” (Powell et al. 2011, p. 1369). Powell, Lovallo, and Fox have identified three approaches to behavioral strategy in the scholarly literature – reductionist, pluralist, and contextualist. Unlike the positivism and objectivism that define the reductionist approach, and the nominalism and pragmatism of the pluralist approach, the contextualist approach is based upon phenomenology, symbolic interactionism, and the social creation of reality.

Sensemaking is a characteristic example of a contextualistic approach and has developed out of a critique of the perceived shortcomings of the reductionist approach to organization and management strategy. Sensemaking is a part of the postmodern tradition by virtue of it taking reality as a social construction which is created by the members of an organization as they share, maintain, and impose their meanings on their environments.

Blatt, Christianson, Sutcliffe, and Rosenthal have described sensemaking as a social process of human agency for creating meaning out of experience that acts: “as a lens that focuses our attention on human agency, equivocality and relationships. It focusses our attention of agency because action is viewed as part of people’s efforts to make sense; on equivocality because sensemaking is triggered by people’s need to understand an equivocal flow of experience; and on relationships as sensemaking is social” (Blatt et al. 2006, 898). The value of sensemaking in the study of strategy and management therefore lies in its utility to serve as a lens to facilitate the analysis of organization as a process.

As discussed above, the environments within which organizations operate can be characterized by complexity. The volume of information available to most modern organizations exceeds their ability to process and understand it. Enacting environments by bracketing equivocal information and events as cues allows organizations to filter available data and thereby promote their capacity – in the words of Starbuck and Milliken – to “comprehend, understand, explain, attribute, extrapolate and predict” (Starbuck and Milliken 1988, p. 51).

The importance of sensemaking lies in its focus on the process of “organizing,” not to “organization” itself. Tsoukas and Chia have explained

the difference between organization as structure as opposed to process. For Tsoukas and Chia: “the organization is both a given structure (i.e., a set of established generic cognitive categories) *and* an emerging pattern (i.e., the constant adaptation of those categories to local circumstances). Institutionalized cognitive categories are drawn upon by individuals-in-action but, in the process, established generalizations may be supplemented, eroded, modified or, at any rate, interpreted in oftentimes unpredictable ways [original italics]” (Tsoukas and Chia 2002, p. 573). The process of organization is sensemaking – it is therefore the process from which the patterns emerge. Understood thus as a process of organizing, the concept of sensemaking as enactment has implications for several aspects of the management of organizations.

In studies of strategy and management, the concept of sensemaking has been frequently applied to the analysis of failed responses to crisis situations and myopia in decision-making. Such studies include Weick’s famous study of failed decision-making in the response to a forest fire at the Mann Gulch disaster (Weick 1993), instances of friendly fire in combat situations over Iraq (Snook 2000), organizational crisis (Mullen et al. 2006), and breakdowns in leadership responses to crisis (Combe and Carrington 2015). Weick has identified a critical dilemma faced by organizations as they make sense of their environments in that in practice: “. . . sorting out a crisis as it unfolds often requires action which simultaneously generates the raw material that is used for sensemaking and affects the unfolding crisis itself. There is a delicate tradeoff between dangerous action which produces understanding and safe inaction which produces confusion” (Weick 1988, p. 305). Drawing upon the understanding that sensemaking is the process that precedes decisions, Snook has highlighted this organizational importance of sensemaking when he observed that it: “underscores the importance of initially framing such senseless tragedies as ‘good people struggling to make sense,’ rather than as ‘bad ones making poor decisions’” (Snook 2000, p. 207).

Recently sensemaking has been integrated into approaches for promoting design thinking and

creativity (Madsbjerg 2017) and identified as a leadership skill in business management (Ancona 2012; Ancona et al. 2007).

Definition

Sexual harassment (sexual bullying, sexual abuse, sexually discriminating behavior, sexually offensive behavior) is probably as old as human species. It was known in Ancient Rome under the term of any accosting, stalking, and abducting which was clearly forbidden. However, it was just around 200 years ago that it was initially publicly recognized, discussed, and fought in modern times as something that is omnipresent, and especially as something essentially immoral even if relevant cultural differences are given, and bad for any victim of it and for any work or business a victim is engage in.

Sexual Harassment

In 1833, an Austrian painter Johann Michael Neder (1807–1882) made the painting “At the tavern” which depicts obvious scene of sexual harassment of a waitress by a guest of the tavern. In the nineteenth century, arts and especially paintings were besides being “art for art’s sake” also sources of social ideas and criticism, and this one was a representation of sexual harassment almost 150 years before it was commonly recognized during the 1970s in the USA (EEOC [2017](#)) and UN and EU by the document “Prohibition of discrimination, harassment, including sexual harassment, and abuse of authority” (EU Council [1976](#)).

As far as Neder’s painting is among the first to depict this obviously immoral no matter if common practice, it represents 200 years of public recognition of sexual harassment as a specific type of non-consensual sexually offensive act and as a specific type of harassment. Important for sexual harassment, by being sexual which is obvious, is that an action by a harasser must be frequently repeated and relevantly influencing the person who is harassed and the work she/he is performing while suffering a harassment. Compared to Neder’s example of sexual harassment, nowadays much less is considered as such.

Many of the following actions may constitute sexual harassment (Webb [1997](#)): wolf whistles, discussion of one’s partner’s sexual inadequacies, sexual innuendo, comments about women’s bodies, “accidentally” brushing sexual parts of the body, graphic descriptions of pornography, pressure for dates, sexually explicit gestures, unwelcome touching and hugging, sexual sneak attacks (e.g., grabbing breasts or buttocks), sabotaging women’s work, sexist and insulting graffiti, inappropriate invitations, sexist jokes and cartoons, hostile put-downs of women, public humiliation, obscene phone calls, displaying pornography in the workplace, inappropriate gifts (e.g., lingerie), pressing or rubbing up against the victim, sexual assault, leaning over, invading a person’s space, etc.

In the period between 1997 and 2011, the number of sexual harassment charges analyzed by the

US Equal Employment Opportunity Commission (EEOC 2017) went down from 15,889 charges in 1997 to 11,364 charges in 2011. Almost 50% of all charges were established to be filed with no reasonable cause. Last but not least, the number of charges filed by males in the same period went from 11.60% in 1997 to 16.3% in 2011.

The overall data in the case of women are to be taken cautiously, no matter if women cases still constitute huge majority of all cases in a given business culture or country, since, for example, the percentage of sexually harassed women according to dozens of various data which may or may not be completely reliable may vary between one in three and one in ten. However, even if the second ratio is closer to the correct one, this presents a real and urgent problem for women as human beings and female employees as employees and for any business public or private. More to that, there's no projection of percentage of not filed cases which, as we shall see later on, in majority cases end with victims' change of job.

In short, and according to EEOC data (EEOC 2017), in 79% of all cases of sexual harassment, victims were women; in 51% of all cases, harassers were superiors; and the places in which it occurs in the highest percentage include business, trade, banking, and finance, and women in these industries on average create 25% of all employees and much lesser on higher managerial positions (Baker 2008; Boland 2005; Clark 2013). However, there is space for doubt concerning the specific professions and sectors of economy, since some new research show that in some quite different sectors, there is a lot of sexual harassment but that in the same time it is not researched at all or researched marginally and poorly, such as tourism (Ram et al. 2016).

Overall losses in business due to all types of harassment, sexual included, are quite hard to calculate because of the data about harassment in principle, and because of the projection of established cases to all probable cases that went under the radar (first of all because harassers are not charged), and finally because of various often quite huge differences in cultures, especially in business cultures as organizational behavior practices and corporate cultures. In the future, it is obviously needed to establish a global criterion

tolerant to cultural differences on the one hand and sticking to this global rule and criterion strictly, which will at least establish reliable data, projections, and perhaps efficient prevention policies.

Given these facts, the following will be explicated henceforth: the description of sexual harassment will be supplied, some contemporary issues surrounding the description, the list of types, and finally some frequently used and effective policies and actions that are applied for sexual harassment prevention. What is global about sexual harassment is only the very general description of it and general condemnation of this shameful practice, while an application of prevention of it, especially in business, established procedures for filing charges, and similar are often under the influence of local cultures which are transmitted to business cultures as in any other part of it, especially to legal cultures and regulations concerning harassment in general and sexual type of it as well.

Description of Sexual Harassment

Many common definitions of sexual harassment say that it is:

[T]he practice of forcing another party to act in an involuntary manner by use of force, intimidation, threat, coercion or some other form of pressure to abuse, intimidate, or aggressively dominate other in sexual manner, or inappropriate threat of punishments or promise of rewards in exchange for sexual favors and it is in most modern legal contexts illegal. (Dromm 2012; McLaughlin et al. 2012; Paludi and Barickman 1991).

By being sexual and harassment, sexual harassment overlaps between harassments and sexual acts in a special way. Namely, not all sexual acts are assaults or offensive acts, and not all harassments are sexual which sexual harassment surely is.

Within sexually offensive acts, some are similar yet quite different such as rape, and within harassments as disturbing and upsetting offensive characteristically repetitive acts, some are similar yet again quite different such as non-sexual workplace, racial, religious, or nowadays online harassment (sexual online harassment is a new

type of sexual harassment, and it will be mentioned separately).

Consequently, it is of utmost importance to describe sexual harassment precisely and effectively in order on the one hand to identify it correctly and to prevent it and on the other hand to prevent its misuse and abuse due to misconceived understanding of it. Sexual harassment as being described legally speaking often doesn't include acts that do not repeat on a regular basis and acts of simple teasing or offhand comments. Further on, it doesn't include other types of harassment which aren't sexual which in practice of prevention can be quite important. Finally, it doesn't include other types of sexual assaults or offensive acts such as rape.

These and other, mainly legal controversies, surrounding sexual harassment, raised criticism of it in legal and other terms (Hajdin 2002; MacKinnon and Siegel 2004). Namely, much confusion can occur, and this is obvious if one counts the dismissed charges for sexual harassment by organizations that are dealing with it (EEOC 2017). Legal cases are completely different story, and they represent especially dangerous field, because neither victims nor harassers often know much about finesse of these criteria and similar cases.

On the other hand, the fact, which recent research shows (McLaughlin et al. 2017), is that women as the major group among victims of sexual harassment, especially during their early careers and working years, do not report it, do not engage in private lawsuits, but rather change the actual workplace environment to put it mildly.

Some further possibilities, like direct and indirect, public or private, and explicit or implicit sexual harassment, make this description issue even more important. In order to show at least some possible practical problems, some of these distinctions will be separately explicated hereafter.

Some Contemporary Issues About Sexual Harassment

EEOC defines sexual harassment quite strictly, and because of that stringency of the definition,

it is quite interesting to see many common misunderstandings of this type of employment discrimination:

It is unlawful to harass a person (an applicant or employee) because of that person's sex. Harassment can include "sexual harassment" or unwelcome sexual advances, requests for sexual favours, and other verbal or physical harassment of a sexual nature. Harassment does not have to be of a sexual nature, however, and can include offensive remarks about a person's sex. For example, it is illegal to harass a woman by making offensive comments about women in general. Both victim and the harasser can be either a woman or a man, and the victim and harasser can be the same sex. Although the law doesn't prohibit simple teasing, offhand comments, or isolated incidents that are not very serious, harassment is illegal when it is so frequent or severe that it creates a hostile or offensive work environment or when it results in an adverse employment decision (such as the victim being fired or demoted). The harasser can be the victim's supervisor, a supervisor in another area, a co-worker, or someone who is not an employee of the employer, such as a client or customer. (EEOC 2017).

Some issues are obvious, and due to the possibility of their occurrence in the practice of sexual harassment prevention, they need to be at least mentioned.

First, sexual harassment is wrong because it is wrong to harass a person because of her/his sex generally speaking. However, sexual harassment as a type of employment discrimination is even more wrong because a person is harassed because of its sex but this isn't done with an end in itself, or only because of it in terms of motive or a reason for action, rather as a means to some business end different from sex, and generally not sexual in its nature, such as an job advancement or not during process of recruitment, during actual work, especially concerning training, achieving results, development and benefits, and finally during ending the work process by any type of employment termination.

Second, sexual harassment doesn't have to be sexual in its nature; rather it is sufficient to be "offensive remarks about a person's sex" or even generally about sex. The crucial word here is "offensive" since it must be intended, performed, and received as "offensive." Namely, not all remarks of this nature are offensive. Some of

them may be quite the opposite as a part of policy of reducing sexual harassment, or a part of a joke that everybody finds funny rather than offensive, and which makes fun of both sexes making mixed-sex working environment more relaxed and normal. However, it is illegal to harass a woman or a man by making general offensive remarks about the whole sex as well. Here it is of utmost importance to notice that even in such circumstances, implicit offensive remarks are possible and performed since harassers are aware of the illegality of making explicit remarks.

Third, in many countries, law prohibits any sexual harassment, but teasing and similar are not to be included, because "harassment is illegal when it is so frequent or severe that it creates a hostile or offensive work environment." The "frequency" of harassment that causes "offensive" work environment and offenses an employee is crucial because basically it is bad for employees and at the end for the whole business and society (because the effects are often spilled over from professional to private lives of employees).

The obvious case is also the one in which victims of harassment are being regularly fired instead of protected and harassers identified and punished. In reality, since they are superiors, there is no one to punish them, especially in private businesses. Such situations are regulated generally by responsible restructuring processes which include various ethical policies (Cascio 2002). The pattern of action or behavior by a harasser is needed to be identified in order to establish sexual harassment, but there is also the similar pattern by a highly probable victim of harassment which is quite important in prevention and also needs to be identified. Such procedures and policies make these actions easy and normal in many organizational cultures.

Fourth, historically speaking, surely sexual harassment was recognized because a particular type of it creates majority of its history, namely, harassing women at workplace by superior men, and in some countries and regions of the world, this is still the most frequent type. However, during the twentieth and twenty-first centuries, women are in the much better situation than before, so the new types emerged. Namely, there

is a harassment of men at workplace by superior women, and this surely is sexual harassment as any other. Yet this may be discussed in a broader context of ways in which women advanced in historically dominantly man's positions and professions unaware that they are becoming man-like bosses, such as middle and top management, and of course of ways of management models in so-called "female ways" of management.

As an addition to this, so to say examples of the vertical sexual harassment, i.e., superior woman/man harassing inferior employees, woman/man, and it may go both ways; there is also horizontal type in which there is harassment among employees at the same job level, sometimes as a tool for advancement in quite competitive work environments.

There is also a type which cuts across different sections of a business and between not directly related employees in core business terms. Finally, there is a type in which an employee is harassed by a client or by a customer (which leads us back to the beginning and Neder's painting). These complicated forms of sexual harassment show that the problems with its definition aren't just of legal nature of the very act, rather as well of its relation to groups outside of an organization in which harassment takes place.

Circumstances and Occurrences

Sexual harassment is omnipresent. It may occur in private and public life; in schools, academia, factories, corporations, government, all state institutions, and professional institutions; and even in NGOs. Probable harassers and victims may be everybody, even a complete stranger. A "street harasser" is a prototype of it (Macmillan et al. 2000). However, in a majority of established cases, a harasser is a person known to a victim and is in some kind of power or authority relation to and over a victim due to various differences between them (in age, sex, occupation, position at the workplace, wealth, influence, or sometimes simple physical strength).

Concerning the actions, it is quite important that a harasser may or may not be at all aware of

his or her actions of sexual harassment, i.e., that he or she is doing something illegal, immoral, and offensive toward a victim. In this respect, sexual harassment should be explicitly forbidden and mentioned in a suitable document addressed to a potential member of a community, an institution, or an organization (school, faculty, firm, company, government institution, etc.).

Also, on the side of a victim, it may be that he or she is completely unaware of what's going on and doesn't know what to do. In this respect, sexual harassment should be explicated to all potential members of any group in order for them to recognize it and react before it becomes seriously frequent and causes harm to all included (treatment of potential harassers and potential victims of harassment may prevent many future situations and contribute to the development of a non-harassment atmosphere within a group as a type of common and normal behavior).

Concerning places and times, sexual harassment may occur almost anywhere and anytime; however, it is more likely that it will occur at those places and during times in which a harasser can effectively use his or her power over a potential victim, i.e., in places and times in which the very act of sexual harassing need not to be completely explicit yet completely obvious and clear to the victim (e.g., a harasser of influence over a victim's development and advancement at the workplace may harass at the place of power such as his or her office in order to make his or her actions completely clear yet implicit in order to escape possible charges).

Given the fact that more and more of our actions are performed online in various types of formal and informal communication, it is not necessary that sexual harassment occurs in physical space since it can occur online. Some research suggests quite interesting facts about online harassment generally, namely, that men are more sexually harassed by being "called offensive names," "purposefully embarrassed," and "physically threatened" while women by being "stalked" and "sexually harassed" (Barak 2005; Maeve 2014). The same research shows that woman and man, no matter if they are harassed in different ways, are both harassed for a sustained period

which is quite important for establishing harassment, especially sexual.

Impact and Prevention

The basic reason for prevention of sexual harassment is because it is a morally incorrect action, and additionally it may include various impacts toward the victim or environment, i.e., causing stress, depression, and similar disorders in victim, and sometimes unbearable life and/or work conditions, and eventually low results at workplace.

Some research report that "severe or chronic sexual harassment can have the same psychological effects as rape or sexual assault" (Koss 1987), and for such victims, some type of therapy is surely needed. In various organizations, sexual harassment directly reflects on work results, decrease of productivity and job satisfaction, etc. However, as said, it is very hard to find reliable data on the amount of this negative influence of sexual harassment on business success.

Given that sexual harassment is a sexual offence and a type of harassment, it should be identified and prevented as any other sexual offence and any other type of harassment, namely, by programs which educate the general population of any group (in families in case it is about private type and in local communities, schools, faculties, workplaces, and local governing institutions in cases it is about public type). It's all about educating and cultivating a group into a new cultural routine or a habit of non-offensive work practices.

Such programs, some of which showed some results, often include ways of identification of potential harassers, and potential victims, and both are made aware of their behavior and attitudes. Such educative activities may lower a general opportunity for any type of harassment and sexual as well. However, there are no 100% effective programs.

Many public institutions, organizations, and companies as well as many private corporations have clear, expedite, and effective procedures for dealing with any and also sexual harassment. Namely, in various codes of conducts, ethical

codes, or similar ethical documents all types of harassment, sexual included, are described and explicitly forbidden. In countries in which the practice is illegal, there is also a practice that the harasser is reported to the police in case if harassment is proven by some formal internal officer or a body of an organization or a company.

The ongoing debates are concentrated between two different solutions for prevention. One says that if an act of harassment went on and solid evidence of it is established, then the whole case should be reported to the police if such action is illegal. If proven, such case would remove the harasser, give some satisfaction to the victim, and strongly influence others in an organization, especially other potential harassers.

Different approach says that creating particular anti-harassment organizational culture and corporate climate would minimize possibility of any harassment and consequently sexual as well. The third option says that both ways should be combined so that in any case of severe sexual harassment, a harasser should be reported, while if smaller cases occur, then a radical change in organizational culture should be made and implemented top-down without exceptions.

Summary

Sexual harassment is a fact. There are harassers and victims. However, in Western societies, the number of cases is falling, while globally it seems that it is constant or rising due to various causes such as differences in cultures among nations with rising population which are connected with poor work regulations, work environment, and organizational culture in general.

As regards criticism of sexual harassment, while in the same time it recognizes the horrible nature of the act toward the individual and the group, still it claims that instating on it as a "sexual" more than "harassing" aspect doesn't produce results. Critics also claim that many "things" are counted as "sexual harassment" but which are "sexual" only accidentally. Namely, in

most cases, it is about the fact that some people do not know how to live, cope, learn, and work with others, so they do what they do, and sometimes they act as sexual harassers among many other offensive, immoral, and sometimes even illegal things they do in order to achieve personal goals in life.

Leaving aside these criticisms, it should be said that severe cases of genuine sexual harassment exist, harassers are proven guilty, and some improvements exist. The fact that the majority of victims in these genuine cases are women (more than 2/3), that the majority of harassers are superiors (more than 1/2), that harassment occurs in the specific sectors of economy and mostly at a workplace, and that the harassers are often engaged in other types of misuse of their power, influence, and similar over inferiors shows that sexual harassment is a part of a broader pattern of misuse and abuse of power of superiors over subordinates generally and only perhaps in particular professions and businesses more than in some others.

No matter how progressive we think of ourselves and of our contemporary twenty-first-century civilization and culture in which we live as its proud members, it is quite illustrative that the Ancient Roman rule still so up to date prohibits and that nineteenth-century painting still so currently describes an activity which we think is fundamentally barbaric and immoral, but which we didn't eradicated so far.

Shadow Trades

Amos Owen Thomas
Stockholm Business School, Stockholm
University, Stockholm, Sweden

Synonyms

Black markets; Exploitative business practices; Illegitimate business; Illicit trade; Informal sector; Underground economy

Definition/Description

Throughout history there has often been a dark-side to legitimate international business, as for example with the slave trade which was an intrinsic part of Atlantic triangle trade in sugar and cotton, or in the opium trade in China in exchange for tea and silk for Europe. Over the twentieth century growing deregulation of global business facilitated the concurrent growth of various shadow trades as human trafficking, money laundering, waste dumping, organ harvesting, contraband smuggling, and arms transfers. While these illicit businesses may seem peripheral and small in comparison with the legitimate global trade in goods and services, the former's operations are closely intertwined in the same supply chains with the latter's.

Forms and Extent

Human trafficking: Estimates of global forced labor which include human trafficking, there were 21 million global victims in the early 2010s. Sexual exploitation which attracts more attention constitutes 20% of this number, while another 70% are

bonded in agriculture, manufacturing, construction, and domestic work. Some trafficked humans end up in legally fraught areas of drug couriering, armed robbery, street hawking, begging, even organ harvesting. Human trafficking is estimated to be worth US\$32 billion, while the victims generate about US\$150 billion in profit for private enterprises producing raw materials and/or products for the global marketplace. While people smuggling and bonded labor may be differentiated from human trafficking, the illicit businesses involved are closely linked.

Organ harvesting: The sale of human body parts tends to be reported regularly in a number of developing-emerging economies, while occasionally in industrialized-developed countries there have been scandals over cadaver sales to hospitals, universities, and research institutes. Given little definitive research, the size and value of the market have to be of widely varying estimate. The need for concurrent surgery has spurred the growth transplant tourism in which the developing-country donor is flown to the developed-country of the recipient, or vice-versa. Contributing to the growth of this shadow trade are the diminished role of government, the diffusion of healthcare standards, and normalization capitalist forms of exchange.

Waste dumping: The trade in waste typically involves the shipping of everything from household trash to industrial chemicals, usually from developed/industrialized economies to developing and/or emergent economies with adverse consequences for the environment of the latter as well as the health of their peoples. More subtle than the dumping of solid toxic wastes but no less lethal is the related field of pollution or the jettisoning of waste into the air, earth, and water with local, regional, and global consequences. Although the Basel Convention exists, this treaty is weak given the directionality of the trade from developed-industrialized to the developing-emergent economies. Research focus has been on the consequences and remedies, not on pre-emption or penalization of the businesses which profit from this dark trade which threatens environmental sustainability.

Arms transfers: The arms trade encompasses nuclear arms on the one hand and the small arms trade on the other, and every type of weapon in-between. The revenue of the global arms export totals over US\$150 billion or about 7.5% of total world trade in merchandise. Despite the efforts of some governments, regional organizations, IGOs, and NGOs to develop policies and initiatives on arms control, the trade is growing. Much of this substantial world trade is conducted by major corporations of developed-industrialized nations and is subsidized by their governments and taxpayers. Furthermore, many leading importers of arms are from developing-emerging economies where such high public spending represents diversion from health, education, and housing services, not to mention economic consequences of inter- and intrastate conflicts.

Money laundering: Deregulation of the financial markets in the twentieth century which boosted global economic growth, also aided kleptocrats of dysfunctional states as well as criminal gangs and terrorist organizations to launder their dubious income. By the mid-2010s global money laundering is estimated to have reached between US\$800 billion and US\$2 trillion, or as much as 2–5% of global GDP. Related is the phenomenon of tax havens with their secrecy laws, which are centers for money-laundering via legitimate banks. Attempts have been made by to black-list tax-havens in micro-states of the developing world though onshore financial centers in the developed world have greater capacity to launder money. Furthermore, many of the other dark-trades are dependent on money-laundering of the proceeds for their effectiveness and this oftentimes bypasses the more established financial institutions.

Interlinked trades: Diamonds, other gems, gold, rare earths, and many other forms of resources mining in conflict-zones are used to fund civil wars. The profits are used to purchase arms from a legitimate industry in the developed world subsidized and supported diplomatically by their governments. Yet another dark trade is the processing and smuggling of hard drugs such as cocaine from and via Latin American

and Caribbean states or heroin from East and Central Asian countries. Often the routes for these drugs into Europe and North America are the same as those used for people smuggling. Perhaps less evident is the impact of the trade in counterfeit pharmaceuticals which, while profitable for their manufacturers, risks the lives and health of their users, resulting in social cost borne usually by governments of developing countries. Thus the shadow trades enumerated in this section comprise a far from exhaustive list, and there are many linkages between the various trades.

Catalysts or Concomitants

Economic differential: The exploitation of people in developing countries by most of the dark trades can be seen directly in the trade in body parts, and human trafficking. This may be seen indirectly in arms and toxic wastes sourced from industrialized countries as well as some emergent economies, for sale to developing countries. Declining agricultural commodity prices set largely by global institutions leaves the farmers in developing countries little option but to grow illicit crops or have themselves smuggled into developed countries to work on subsidized farms. Money laundering is derived in part from the smuggling of drugs into the developed world for sale at prices much higher than paid for their production in developing countries. Yet the rise of capitalist free-market ideology globally inhibits government intervention in the economy in a way which might affect all businesses, legal or otherwise.

Government incompetence: Exploitation of labor is patently possible when neither the laws of the host-country or the home-country apply in free-trade zones, ostensibly to create jobs at the cost of forgoing tax revenue. Conflict zones where governments or rival armed groups, even foreign occupiers exploit people and resources which then enter the global supply chain of the jewelry industry, industrial processes, food, and household electronics. Disenfranchisement from legitimate

opportunities to improve their economic lot compels people to create and participate in the quasi-legal or extra-legal “second economy.” Embargoes imposed by countries invariably spawn large-scale smuggling, ironically often with the collusion of parties concerned in the conflict. While governments or influential persons in it are sometimes direct participants in shadow trades, if only by being corrupted to overlook them, more often than not facilitating these unwittingly either by incompetent inaction or misguided policies.

Corporate culpability: Supply chains involving child labor or forced labor, minerals from war-zones, dumping toxic wastes from manufacturing process or discarded products, pollutants left in the country of production often result in products marketed legitimately globally. Furthermore, many legitimate businesses share the same supply chains, use the inputs of or are used by shadow trades, with or without their knowledge, and are thus tainted. Human trafficking and organ harvesting, for instance, use travel agencies, ships, and airlines, some of which might deem these lucrative business side-lines. Legitimate logistics may be done on behalf of corporations which might be in ethically questionable trade such as in arms or waste. Perfectly legitimate businesses may have owners that use them as a cover for their dubious businesses as in money laundering. Advertising and marketing by multinational corporations then must share some responsibility for fostering dissatisfaction among citizens of developing countries with their standard of living, one consequence being people smuggling of economic migrants to the industrialized world. Only the consequences of adverse publicity for profitability and stock value seem to drive corporations towards corporate social responsibility.

Summary

While international crime is defined as activities that nation-states perpetrate on other nation-states or parts of their own and others, dark trade is

perpetuated by firms, organizations, informal groups, and even individuals. These take advantage of regional political-economic integration, trade treaties, renewed nationalism in new states, break-away provinces, dysfunctional or non-functioning states. By definition of being shadow trades, these are neither readily discernible nor their links clearly manifest, for researchers to access and confirm definitively. Nonetheless, a fair amount is known or reasonably conjectured about the nurturing contexts for these illegitimate businesses and complex web of complicity in their operations by governments and corporations. Current approaches of regulation, law enforcement, and charity do not adequately address the growth of the shadow trades is manifestly evident. Legitimate businesses need to be proactive against shadow trades still prevalent in the twenty-first century that nonetheless share the same supply-chains, financial institutions, communications technologies, and favorable trade treaties. The uncritical promotion of international trade as the means of co-opting developing countries into the capitalist world economy on the questionable promise of sustainable economic growth needs to be challenged.

Shared Community-Based Governance

Mara Del Baldo 

Department of Economics, Society and Politics,
University of Urbino Carlo Bo, Urbino, Italy

Synonyms

Local governance; Multi-actors and multilevel policies; Multilevel governance; Participatory governance; Public-private governance; Territorial governance

Definition

A shared community-based governance is the outcome of a decision-making process nurtured and delivered by formal and informal networks of stakeholders. Networks are formed by actors with a strong territorial connection and include public entities, large companies, small- and medium-sized businesses and not-for-profit organizations that are motivated to cooperate with the objective to improve the social, cultural, and productive system. They are based on trust and shared values that benefit the development of corporate and citizenship initiatives oriented to a common good. Many public and private policies can be effectively realized at the national, regional, and local level to support corporate social responsibility (CSR) and sustainable development goals (SDGs). The multilevel and multi-stakeholder approach to a responsible and sustainable growth calls for a shared community-based governance and can be explained as a model that is bottom-up driven, based on participatory governance systems whose protagonists are embedded in a local community.

Introduction

During the last few decades, a developing field of research on CSR and sustainability have been nurturing mainstream perspectives, supporting the stakeholder theory (Freeman et al. 2010) and considering the interface with innovative concepts of governance, such as private-public governance, multilevel and territorial governance, among others. These new perspectives should be investigated conceptually and empirically because they are founded on a mutually reinforcing alignment of multilevel and multi-actors social responsibilities. “Sustainability requires institutional contexts that enable actors to enact socially responsible principles and practices as well as apply and develop social capital and creativity” (Ashley and Crowther 2012, p. 182). The advancement of participatory governance has been highly suggested by the European Commission and the United Nation as a driving force of CSR by

stressing the significance of cooperation at the regional, sub-regional, and local level between the different actors engaged (UNGC 2007).

At the European level, the White Paper on multilevel governance has been delivered to the member states and local and regional authorities to solicit partnerships and execute policies (based on vertical and horizontal exchanges among social actors from diverse institutional spheres and jurisdictions). The theoretical construct of shared governance has been put into use by networks of local actors in several experiences of territorial social responsibility (Del Baldo and Demartini 2012).

Various approaches of shared governance have been distinguished based on the coordination of multi-actor-driven policies aimed at sustainability that have been implemented at different territorial levels, such as regions, provinces, or towns (Midttun 2005). These approaches indicate the shift from novel public management policies to network governance policies that are characterized by the involvement of public, private, not-for-profit and non-governmental entities, as well as private citizens in fulfilling public services and striving for the common good. They give rise to social innovation at the micro, macro, and meso level and enrich social capital, contributing to problems being solved and opportunities being identified through collective actions (Ostrom and Ahn 2009; Voorberg et al. 2015).

Key Issues

Scholars and policy makers are aware that political, social, and production processes and interactions occur at the local level. The function of the space – the territory – is not only geographic but also ecological, social, economic, and cultural in that it mainly supports the interactions and relations among the members of an ecosystem, which is distinguished by a shared cultural identity.

The model of shared governance is based on social dialogue, democratic participation and socio-economic inclusion. These contingencies are incited by intangible factors, such as rules, values, norms, traditions, and knowledge that establish the human, structural, and relational

capitals inset into territorial communities (Demartini and Del Baldo 2015). While sharing values and behavior patterns bring about a climate of trust and collaboration, the paths of sustainable development are based on the aptitude of public institutions, entrepreneurial associations, companies, not-for-profit organizations, universities, banks, etc., to take part in and activate networks that are conceived as knowledge assets that influence the territorial processes of value creation (Lerro and Schiuma 2009). In this case, knowledge is translated into a shared language and actions owing to circular knowledge exchange and dissemination. As a result, territorial capital can be understood as the output of tangible and intangible assets stemming from individuals and organizations participating in networks belonging to a definite community. Community-based networks (including municipal and regional authorities, consumers, enterprises, not-for-profit associations, universities, civic organizations, etc.) are guided toward a model of sustainable economic development. In such contexts, each actor plays a pertinent role: public institutions are responsible for soliciting, regulating, and supervising responsible governance; not-for-profit organizations and citizens can encourage and “educate” both public and private companies, and the latter actively contribute by enhancing the socio and economic conditions of the local area. The integration of reciprocal perspectives, needs, and expectations allow actors to weather fragmented views and practice a systematic thinking, which is the key characteristic of shared governance.

Therefore, the territorial competitiveness of sustainability is a pathway promoted by a plurality of actors whose relationships drive the use of a model of a shared community-based governance. This type of cooperative and participative governance generates more engagement with citizens and other stakeholders involved at the local level.

Future Direction

There is a global need for territorial governance approaches based on multi-actors and multilevel

policies that can achieve sustainable development goals (UN 2015). Secure and collaborative relations between different kinds of organizations proffer the foundation for mixed networks (Gerencser et al. 2008) formed by actors that play various roles and act in synergy.

Shared governance enables the transition from government to governance and to interactive planning and multilevel shapes of cooperation founded on trust and transparency. Therefore, it necessitates an explicit shift from a top-down approach to a bottom-up approach (supporting vertical and horizontal subsidiaries) and multilevel cooperation. The shared governance model depends on the territorial declination and factual implementation of CSR and sustainability. It also signals the importance of the local community’s commitment to participative governance and the sharing of knowledge, which enhances community learning and co-creation that in turn drives sustainability. Moreover, it yields new practical and conceptual tools used to overcome traditional centralized models of public management and apply cooperative and delocalized mechanisms for sustainability management.

Concurrently, these innovative trajectories underline the need for theoretical constructs that consider the centrality of the territory and the embeddedness of actors engaged in sustainability-oriented projects.

Summary

Sustainability in society and economy calls for public and private actors to establish socially responsible principles in policy making, finance, education, consumption, taxing, pricing, and use of environmental assets. Intangible factors like social and relational capital represent the soft asset, which favors the orientation of companies, institutions, and organizations rooted in a territorial community toward social and responsible paths of governance capable of enhancing social cohesion and generating social and economic innovation. Territorial paths of shared governance activated by local networks of actors that share a common set of values and are oriented to mutual

goals are capable of leading and preserving sustainability over time.

[Common good](#); [Creating shared value](#); [Shared good](#); [Thick value](#)

Definition

Shared value is a sustainable model for production, consumption, and exchange so that all the actors in the value cycle benefit environmentally, socially, and economically.

Introduction

Values are related to things worth wanting. With the things worth wanting, life is supposed to be better. Dreaming of and making a better future is based on values.

An *intrinsically valuable thing* is worth pursuing for its own sake. It is unconditionally valuable, that is, it is valuable in every circumstance. Happiness – if defined broadly – can be such an intrinsically valuable thing. *Instrumentally valuable things* pave the way for a better life, but they are not valuable by themselves (Shafer-Landau 2010, 18–55). More fulfilling jobs, less pollution, and more equal pay are examples of instrumentally valuable things.

Capitalism contains an assumption of psychological *egoism*; this means that human beings are motivated by self-interest. The opposite of self-interest is *altruism*, which means that people desire to help others (Shafer-Landau 2010). Altruism is based on the fact that no one is all-powerful. People are stronger together than alone. This raises a question of whether shared values would be more beneficial for the common future of humankind on Earth than egoistic values. The question is with whom should we share our values? In Table 1 we demonstrate possibilities for value sharing in its widest scale.

In the circumstances of a finite Earth the transition from surplus value to negative value is more evident. Resource depletion, waste, and toxification create negative value. The maxim of

negative value is climate change, because it poses a fundamental threat to the economy itself (Moore 2015). How can we create “value that matters, value that lasts and value that multiplies?” (Haque 2011, 34). In other words, the critical question is how can we share value with customers, business owners, employees, society, and global development on Earth?

Shared Value in Sustainability Management

The use and meaning of value in economics varies a lot. Value is often determined narrowly by the dynamics of price due to scarcity and preferences (Mazzucato 2018). A new way to think and act is a move from seeking the profit of one toward benefiting many (Matinheikki et al. 2017). Value is shared when it benefits many.

Shared value has its roots in Corporate Social Responsibility (CSR) (Bowen 1953).

CSR relates to “economic, legal, ethical, and discretionary expectations that society has of organisations at a given point in time” (Carroll 1979). Shared value is an “extension of organizational ethics” (Davis 1960).

Shared value is about thick value, the opposite of thin value that focuses only on profit, growth, and shareholder value (Haque 2011). Shared value is “the extent to which partners have beliefs in common about what behaviors, goals, and policies are important or unimportant, appropriate or inappropriate, and right or wrong” (Morgan and Hunt 1994, 25). Michael E. Porter and Mark R. Kramer (2011) define shared value as policies and operating practices that enhance the competitiveness of a company, and, at the same time, advance economic and social conditions in the communities in which it operates. Michael E. Porter and Mark R. Kramer’s (2011) definition deals with policies and practices on companies and communities. Shared value enhances the competitiveness of a company and it also advances circumstances of people living in the communities.

John W. Forje (2007) uses the concept of shared values in the context of public policies

Shared Value, Table 1 Aspects of sharing values. Adopted from Salonen (2013, 2050)

I	Human reality	Organic
My family		
My friends and relatives		
People in my country		
All people	Human reality and nonhuman reality	Organic and abiotic
People and animals		
People, animals, and plants		
Ecosystems		
Planet Earth		

and global development: “A partnership of shared values must be constructed for the common good.” Governments put the interests of the poor first by “pushing forward the virtues of democratic governance, partnership, participation, and benefit-sharing among the key stakeholders,” that is a developmental democratic state (Forje 2007).

Kristen M. Watrous, Ann H. Huffman, and Robert D. Pritchard (2006) have studied shared values in organizational behavior. They showed that “shared values are relevant throughout an employee’s tenure with an organization: from recruitment, to hiring, to socialization, to turnover.” Their results also emphasize the importance of shared organizational values (Watrous et al. 2006.) Murray A. Rudd (2000) also shares the idea that organizational unity and shared values cooperate. The most important prerequisites for the creation of shared value are “shared vision and common objectives” (Rudd 2000). Juri Matinheikki, Risto Rajala, and Antti Peltokorpi (2017) also stress shared vision in an organization. Existing practices should be reformed by forming a strong shared vision and putting it into action (Matinheikki et al. 2017).

Shared values between employees and management help the understanding of a vision of the organization. Shared values are created through a deep feeling of belonging and by dialogue (Turulja and Bajgorić 2018). Ilona Skačauskienė, Denisa Hrušecká, Aušra Katinienė, and Martin Čepel (2018) also share the idea of knowledge being a key factor of success for any organization. Requirements for employees’ knowledge have been rising, especially with regard to “the widely discussed fourth industrial revolution in the emerging network economy and knowledge society.” They remark that members of an organization are the key actors to create synergy by collecting, assessing, and storing unique knowledge (Skačauskienė et al. 2018).

Shared Value in the Future

The framework of shared values has focused mainly on the economic and social aspects of

sustainable development. Three major groups of shared value and co-benefits of actions have been company, society, and stakeholders (Jonikas 2013). The latest research concerning shared values focuses on, for example, new ways of authentic assessment in *work integrated learning* in order to enable students entering working life (Young et al. 2019), *networks* and *stakeholders* involved as participants in value creation processes (Ketonen-Oksi 2018), *knowledge management* as a strategic resource (Skačauskienė et al. 2018; Turulja and Bajgorić 2018), and *social responsibility practices* as a competitive advantage (Miralles-Quirós et al. 2019; Na and Kang 2018).

In the midst of current environmental challenges, shared value should also be related to shared responsibility, which includes an environmental aspect (Hecht et al. 2012). The Sustainable Development Goals – Agenda 2030 set legitimate consensus norms for the common future of humankind (UN 2015). There is already a lot of good will, but still a lack of shared understanding in the multidisciplinary creation of a sustainable future. In order to shape hope for the future, we have demonstrated the value cycle of shared value with multiple co-benefits in Fig. 1.

The core of shared value is in customer-orientation, because, in a long run, there are no firms without customers. The modern customer is a participant in processes that create information on behavior intentions and this information gained, assembled, and delivered will create new value. “Shared value has a significant effect on behavior intention, and a distinctive competitive advantage has a significant effect on behavior intention” (Na and Kang 2018). Customers ask why they need this product or service offered to them. If they trust that the offered product or service will help them to have good life, it is of interest. Also, they may wonder what problems does a company fix in society? Does it exist for society or only for owners? What is the purpose of the company from the point of view of society? Due to shared value, for example, public health may benefit (Jin 2018).

In order to have shared value, shareholders ask: why does their company exist? By creating

Shared Value,

Fig. 1 Value cycle of shared value with multiple co-benefits

solutions for the sustainable future, they the company may have better reputation, and the possibility to have a competitive advantage and profit (Mohtsham Saeed and Arshad 2012). Thus, shared value also includes benefits for employees by offering a workplace. More often employees also ask: why do they appreciate the work they do? If they have good reasons to wake up and work for the company, their intrinsic motivation is better. They may also feel that they have fulfilling and meaningful work (Triziner et al. 2011; Valentine and Fleischman 2008).

In order to increase shared value, we human beings may ask: what future generations will remember us for? Benefits for the planet are related to global development goals, such as Agenda 2030, which are targeted to ensure diverse environments, secure natural resources, and to combat climate change. Without a healthy environment human dignity and equality is not possible to reach. A healthy environment is also a key to peace. Societies that are peaceful, just, inclusive as well as free from fear and violence are the most prosperous basis for shared value (Salonen and Åhlberg 2012; Horobet and Belascu 2012; UN 2015; Fukuda-Parr 2019).

It is possible to establish the sort of value sharing that incorporates co-benefits between customers, shareholders, employees, society, and the

Earth. This may mean, for example, that owners of the grocery store decide to increase selling locally produced organic vegetables. By doing so their business embraces different benefit perspectives: “money spent on a consumer choice benefits the local community, food and nutrition promote public health and animal well-being, and consumer choice maintains biodiversity and helps establish global food security.” (Salonen et al. 2014, 77).

Summary

Values are something worth wanting, either for their own sake (intrinsically valuable things) or as a way for a better life (instrumentally valuable things). Values deal with egoism (self-interest) and altruism (helping each other). Value is shared when it benefits many. Moreover, it can benefit both human reality and nonhuman reality on the individual, societal, and planetary level. New trends seem to be embedding shared value discussions in work integrated learning, networks, knowledge management, and shared responsibility, which includes an environmental aspect. These themes are increasing as inclusive societies free from fear and violence are the most prosperous basis for shared value.

Definition

Corporations are frequent targets of activism (Briscoe and Gupta 2016; Goranova and Ryan 2014; Greenwood and Schor 2009; Kahan and Rock 2010; Renneboog and Szilagyi 2011). *Activism* can be defined as “a doctrine or practice that emphasizes direct vigorous actions especially in support of or opposition to one side of a

controversial issue” (Merriam-Webster 2020). Historically, activism has developed and been studied as *financial* and *social activism*, with increasing interest in understanding the direct and indirect effects it has on companies (Briscoe and Gupta 2016; McNulty and Nordberg 2016; Yue et al. 2013). The nature, goals, and actors of activism include financial, social, shareholder, and stakeholder activism. *Financial activism* is rooted in the 1980s’ rise of institutional investors and aims to protect shareholders’ interests and increase shareholder value (Goranova and Ryan 2014). It is typically exercised by *shareholders*, investors in a company, and often referred to as stockholders, as they hold stock (or shares) in the firm. *Social activism* dates back to the 1960s’ civil rights movements. At the time, it was exercised by civic society with the main goal of pushing a broad range of social issues onto the agenda of states and governments (Reid and Toffel 2009). Over time, it evolved to include a broader range of issues (such as environmental conservation practices, social responsibility practices, abortion rights, and special groups’ rights) raised by a wider group of activist (beyond civic society), increasingly targeting corporations (Aguilera et al. 2015; Berry 2003; King and Pearce 2010). Freeman (1984) introduced the term *stakeholder* into management language, and social activism has often been described as stakeholder-centered (Bundy et al. 2013; Goranova and Ryan 2014). The term *stakeholder(s)* refers to any group affecting or being affected by company behavior (Freeman 1984) or anybody holding a legitimate stake or interest in a firm (Donaldson and Preston 1995).

Introduction

The development of activism targeting corporations has been and remains of great interest to management scholars and practitioners as well as policy makers, given that it can be a powerful force affecting organizational policies and practices. Activism is on the rise and has been found effective (Becht et al. 2009; Briscoe and Gupta 2016; Davis and Thompson 1994; Goranova and

Ryan 2014; Kahan and Rock 2010; Greenwood and Schor 2009; Renneboog and Szilagyi 2011; Shi et al. 2018). Many studies have sought to understand how activism influences company-level actions, indicating that investors have an effect on a broad range of company activities such as firm's innovation, mergers and acquisitions, and the creation of strategic alliances and strategic decisions in general.

Financial activism exercised by shareholders has had considerable effects on companies (Gillan and Starks 2007; Goranova and Ryan 2014; Thomas and Cotter 2007). Historically, shareholders in the USA were first granted the right to submit financial resolutions in 1942 (SEC 1942). However, in the 1970s, a US court ruled that companies had to include social issues proposals from their shareholders in their proxy statements, a landmark decision that paved the way for shareholders' *social activism* in the broadest sense, pressuring companies to improve their societal and environmental impact. The 1980s saw the rise of institutional investors which are a type of shareholder (Proffitt and Spicer 2006). Shareholders can include individuals, families, institutional investors, pension funds, hedge funds, nongovernmental organizations (NGOs), and religious groups. Shareholder activism of financial nature can take the form of direct confrontations with boards of directors and management to express frustration or dissatisfaction with a company's decisions or structures, for instance, the successful, lengthy campaign of Oracle shareholders aimed at cutting CEO Larry Ellison's compensation (Waters 2017). Or, it can also unfold as formal battles to change a company's strategy and/or board composition, as in the case of the battle mounted by Nelson Peltz, owner of 1.5% stake in Procter & Gamble, to win a seat on the board and change the company's corporate strategy (Nicolau and Dye 2017).

In the beginning, financial activism was mainly exercised by large public pension funds, such as CalPERS, the California Public Employees' Retirement System, one the largest in the world according to the 2018 Global Pension Asset Survey (Thinking Ahead Institute 2019). However, institutional investors are a heterogeneous type of

shareholder, and over time many of them have become activists. These include pension funds, mutual funds, insurance companies, hedge funds, indexed funds (such as BlackRock, Vanguard, or State Street), a variety of financial intermediaries and Sovereign Wealth Funds (SWFs), and state-owned investment funds such as Norway's Government Pension Fund Global, the New Zealand Superannuation Fund, or the Abu Dhabi Investment Authority (OECD 2011). In the 1990s, hedge funds also entered the activism stage and became known for campaigning on an agenda of shareholder-value maximization, seeking financial performance (as opposed to social) and requiring companies' immediate action (Bratton 2007, 2008; Cheffins and Armour 2011). The CFA, the global association of investment professionals, defines hedge funds as "pooled investment vehicles that can invest in a wide variety of products, including derivatives, foreign exchange, and publicly traded securities" (CFA Institute 2020). Given the power of corporations, shareholder activism has become a force that companies need to deal with, and institutional investors now play a critical role in the strategic, global movement of shareholder activism (Aguilera et al. 2016).

Social activism initially developed in the form of shareholders' mounting campaigns for issues of social nature, either in the company's annual general meeting (where shareholders and the board of directors typically meet to discuss and review company's affairs) or directly with the boards of directors (Sjostrom 2008; Tkac 2006). Over time, this type of activism has increased steadily and has influenced a wide range of topics including the social governance of corporations, corporate environmental impact, corporate social responsibility (CSR), and gender issues (Ferri and Sandino 2009; Lee and Lounsbury 2011; Thomas and Cotter 2007; Pye and Pettigrew 2005). Shareholder activism of social nature has also received the support and endorsement of other *stakeholders*, for instance, NGO or unions (Greenwood 2007). Religious organizations such as the New York-based Interfaith Center on Corporate Responsibility have been instrumental in legitimizing and supporting

shareholder proposals on human rights issues and labor standards, while labor unions have successfully campaigned for workers' interests even at the expense of shareholder value-maximizing goals (Agrawal 2012). When directed toward large corporations, particularly multinationals, shareholder activism has also better chances of capturing media's attention, which in turn might facilitate a campaign's success and its spillover effects to other companies (Thomas and Cotter 2007). Since the definition of stakeholders is broad, efforts have been made to identify a core set of stakeholders whose participation in companies' affairs allows it to survive. This group is often referred to as *primary stakeholders* (Clarkson 1995; Eesley and Lenox 2006; Shropshire and Hillman 2007) and includes shareholders, employees, customers, and suppliers, as opposed to *secondary stakeholders*, such as governments, community activists, advocacy groups, religious organizations, and NGOs (Clarkson 1995). In general, secondary stakeholders do not have a formal, contractual relationship with the company (as is the case for primary stakeholders). Shareholders are often considered as primary stakeholders, as holding shares in a firm is seen as having a formal bond or contract with that firm. However, in common management lexicon, a difference of terminology is normally made between shareholders and stakeholders, as shareholders are not regarded as a type of stakeholder, rather as the investors or owners of the company, hence commonly considered in a class of their own. Therefore, in this chapter, we maintain both terms *shareholders* and *stakeholders*. Ever since the 1960s' civil rights movements, stakeholders (both primary and secondary) have not only supported shareholder activism of social nature, but they also started to directly target corporations, governments, universities, and hospitals with social and financial objectives (Briscoe and Gupta 2016; Davis and Thompson 1994; Rao et al. 2000; Soule 1997; Van Dyke et al. 2004).

Key Issues

Although activism has been studied into two parallel streams (financial and social), in practice

activist shareholders and stakeholders increasingly raise both financial and social concerns (O'Rourke 2003; Goranova and Ryan 2014; McNulty and Nordberg 2016). The boundaries between financial and social activism are increasingly blurred, and it is becoming more difficult to draw a line between social and financial claims. For instance, campaigning for employees' well-being or for flexible hours can be seen as a social goal; however, employees represent a company's human capital and generate revenue and costs. Consequently, where should the line be drawn on such campaign? Is it a social or a financial goal, given that human capital is at the heart of value creation and competitive advantage but well-being and flexible hours are also seen as a key part of work-life balance? This gives rise to a new type of activism of mixed nature. In essence, in the twenty-first century, financial actors such as investors or shareholders, traditionally behind financial activism, are becoming increasingly active in social matters. Most recent examples of this transformation are Allianz Global committing to increase social impact investment (Gordon 2018) and BlackRock urging CEOs to contribute to society (Mooney 2018). In its most general form, this new type of shareholder activism "means nothing more than an active, engaging shareholder who does not simply consider the investment made as purely financial but as strategic" (Ringe 2018, p. 388). At the same time, social actors (such as other stakeholders), long focused on social goals, increasingly campaign for issues that, although social on the surface, entail a great potential of change in the fundamentals of how a business is run and operates. A recent example is offered by Google's CEO Sundar Pichai announcing the company would be stepping back from plans of a possible relaunch of its search engine in China, following Google's employees' activism for more transparency and ethical behavior (Bradshaw 2018). This new type of activism also features shareholders and stakeholders regarding their interest in a given firm not only as financial or social but related to a broader set of issues of profoundly mixed financial, social, and environmental nature. Examples are employees caring not only

for their compensation but also for their emotional attachment to their company and its values (as in the above-described example of Google) or consumers going beyond price points in their decisions and campaigning for the certification of the organic origins or traceability of a product's ingredients. Examples of activism of blurred nature and actors on a global scale are the Socially Responsible Investment (SRI) and the Benefit Corporation movements. SRI is an investment approach that makes use of financial and nonfinancial criteria in investment decision-making, with nonfinancial criteria being its key characteristic. SRI has become known for considering a variety of issues often referred to as "Environmental, Social, and Governance" (ESG) as part of investment decision-making (Kölbel et al. 2018). Although SRI originated in the 1920s with religious groups stating that they would exclude from their investments "sin shares" such as alcohol or gambling, it gained momentum in the 1960s with the civil rights movements and the Vietnam War (Guay et al. 2004). Over the last 10 years, SRI has developed into a mainstream investment approach supported by some of the world's largest religious organizations and institutional investors, such as the Church of England, ShareAction, Hermes Funds, BlackRock, Vanguard, Ontario's Teachers Pension Fund, Axa Investment Managers, and Aberdeen Asset Management. Two international agreements have greatly contributed to this development: the UN Sustainable Development Goals (United Nations 2015a) and the Paris Climate Agreement (United Nations 2015b). An example will help to clarify the importance of this shift in the nature and actors of activism. A manufacturer of solar panel might achieve a certain level of carbon emission savings depending on its revenue or turnover. Investors and stakeholders campaigning for a broader, positive company impact on the environment can increase it by supporting management's strategic decision-making to scale through infrastructure or human capital or innovation investments so that it is able to increase solar panels'sales and/or make the panels more energy efficient and therefore increase carbon emission savings. Another

example is offered by investors who have announced they will be divesting from industries heavily linked to fossil fuels, forcing companies to innovate and shift to sustainable and renewable energy sources. The second example of activism of blurred nature of global scale is the Benefit Corporation movement, one of the most remarkable developments of the last decade (Mayer 2017). Following growing dissatisfaction among business and investors with shareholder primacy, the Benefit Corporation movement has been successful in influencing legislators, initially in the USA (including the important Delaware jurisdiction) and subsequently in other countries, to allow the incorporation of a company as public benefit corporation (B-Corporation) (Alexander 2016; Mayer 2016). This represents a very recent and key development, allowing a new corporate typology with a formal public and social purpose, along with commercial and financial goals (Steingard & Clark 2016). As of September 2020, 3564 companies had become B-Corp certified (B-Corporation 2020). In 2017, French food and beverage consumer group Danone became the first large, multinational corporation to announce its intention to apply for B-Corporation certification (The Economist 2017).

In view of the above-described developments, many argue for bringing the fields of social and financial activism closer together and for relaxing the, at times, rigid definitions of *activism*, *shareholders*, and *stakeholders* (Briscoe and Gupta 2016, Goronova and Ryan 2014). These calls lead to another important consideration. The boundaries of financial and social activism and the types of actors and scopes of activism are increasingly blurred, something that scholars such as Guay, Doh, and Sinclair (2004, p. 128) have noted, as they define shareholder activism as "a mix of SRI, corporate governance, and stakeholder capitalism." Consequently, studying, theorizing, and discussing activism in compartmental terms no longer reflect the reality of the twenty-first century. In addition, even the classification of stakeholders as primary and secondary no longer reflects reality, as the social, political, and financial weight of so-called secondary stakeholders (with or without a contractual bond with a

company) can match or exceed that of primary stakeholders.

Summary

Activism of blurred nature will continue to characterize this century, raising important questions in regard to the often-assumed antagonism between shareholders and stakeholders and between activists and corporations. Activism of blurred nature also raises new perspectives on the recurring question of in whose interest a company should be managed and how corporations can be a force for good, purveyors of economic development, social cohesiveness, and protection of the environment. Obtaining financial returns is in itself a legitimate goal for those who take risks, invest money in business enterprises, and expect returns on their investments. Generating financial returns is also a key responsibility of those entrusted with the governance and management of company affairs. However, in the context of the grand challenges of the twenty-first century (societal tensions, unrest and inequalities, and the climate crisis), shareholder value maximization should be far from being the only objective of activists and corporations. Engaging and managing shareholders and stakeholders who can or have become activist in various shapes and forms increasingly represents a key corporate activity which relates to risk management and corporate resilience, demands management and board attention, and is ultimately related to value creation for investors and for society. This, the future challenges of shareholder and stakeholder activism, may relate to the need for a fundamental shift in our way of thinking about the broader purpose of capital, the purpose of business, and therefore the purpose of corporations (Emerson 2018; Meyer 2016, 2017; Starbuck 2014). Since the 2008 financial crisis, a growing chorus of activist voices have been urging governments, investors, businesses, and society to move away from short termism and the obsession with monthly-quarterly financial returns and to embrace a longer-term way of thinking around value creation for investors and society (Barton and Wiseman 2014). Reengineering a system that

for the last decades has been functioning on short termism is certainly not easy. However, thinking that business and capital should serve society and not vice versa might provide a good starting point and a direction for an ambitious yet very necessary change of our system of wealth creation and distribution.

Synonyms

Corporate democracy; Shareholder franchise; Stakeholder democracy

Definition/Description

Shareholder democracy, an off-shoot of the “shareholder primacy” approach to corporate governance, seeks to increase the role of shareholders in management and decision-making in the corporation. The core idea is that shareholders should regain some of the power that was lost to directors as a result of the rise of management and the board of directors in corporate decision-making. Shareholder democracy sees a parallel between the positions of management of the corporation and the management of democratic societies and suggests that shareholders should have more control and a more active role in the affairs of the corporation.

Shareholder democracy, its advocates argue, is necessary for several reasons, including increased accountability of corporate managers, avoidance or reduction of agency problems and conflict of interests between shareholders and managers, and the role of shareholders as the residual claimants of the corporation.

The broader agenda of shareholder democracy includes enhancing shareholders' voting power, strengthening shareholder advisory resolutions, allowing derivative suits and stock ownership consolidation in institutional investors, and creating say-on-pay rules, shareholder advisory committees, and proxy advisory firms.

Introduction

Corporations are among the most efficient vehicles for conducting business. Through the incorporation process, an incorporator creates a juridical person that the legal system recognizes as an independent person with different rights and duties. This juridical person is styled “the corporation,” a critical actor of contemporary capitalism.

Corporate persons, however, do not act independently of the human persons who incorporate, operate, and make strategic decisions for them. They are fictional entities and, as such, require human persons to make decisions about acquiring rights and duties. A corporation is a

legal vehicle steered by someone. Whether shareholders or directors, one or more human persons is always behind the decisions of the corporation.

Two bodies of the corporation have been traditionally entitled to make corporate decisions: the board of directors and the general meeting of shareholders. What decisions belong to each of these bodies, and therefore what decision power is allocated to each, is a contested matter. Some contend that the corporation's decision process must prioritize shareholders because the corporation must serve the interests of this group ("shareholder primacy") (Hayden and Bodie 2010). Conversely, others believe that the board of directors should be the locus of corporate decision-making as it is best positioned to steer the course of the company ("board primacy") (Hayden and Bodie 2010).

The concept of "shareholder democracy," while acknowledging that boards of directors play an active role in the corporation's decision-making process, holds that shareholders should retain some power over corporations including increased decision-making.

Shareholders and Democracy

The concept of "shareholder democracy" suggests a political parallel between the state and the corporation. This parallel refers to the idea that in the same way that people entitled to a vote in a democratic society define the direction of the country, people entitled to a vote in a corporation should determine the course of the company (Duffy 2002; Latham and Emerson 1952). Although the concept of "democracy" may seem strange in the realm of private corporations, it is a concept that evokes the idea that directors, just as elected politicians, ought to be constrained by the will of the voters, in the case of the corporation, the shareholders (Duffy 2002; Schwartz 1983).

Some authors have argued that "[b]ecause shareholder democracy has become an integral and growing part of a broader democratic process, undermining shareholder democracy

results in undermining the democratic process in our society as a whole" (Matheson and Nicolet 2019). Thus, democratic theories and processes which underpin democracies elsewhere ought to be reinforced and extended into other contexts, including the corporation. Other authors have differentiated the "democratic" systems of the corporation and the state. Differentiating factors include, first, that not every stakeholder has a vote in the corporation, whereas all adults have a vote in a democratic society (Duffy 2002). Second, unlike shareholders, voters in a democratic society have equal voting powers (Duffy 2002). In the corporation, some shareholders may hold significant blocks of shares and so have inordinately large voting rights. Finally, the mobile nature of the right to vote differentiates "democracy" in corporations and states (Duffy 2002). In corporations, shareholders can sell their shares, transferring voting rights and duties to purchasers.

Shareholder Democracy: Definition

Although "shareholder democracy" is not a single, undisputed concept (Garrett 1956; Schwartz 1983), it refers broadly to the idea that shareholders should regain some of the power over the corporation that has been lost as a result of the increased power of the board of directors in the management and decision-making of the corporation. It suggests that shareholders should have more control and a more active role in the affairs of the corporation (Garrett 1956; Gower 1955) – contrary to the ideas underpinning the "board primacy" approach.

Notably, "[s]hareholder democracy refers to the ability of shareholders to dictate or influence the policy, governance, functions, and decisions of the corporation, either directly or through the board of directors and management, as a result of shareholders' ownership rights" (Matheson and Nicolet 2019). Consequently, shareholder democracy "attempts to give the ordinary shareholder a meaningful position in his [sic] relation to modern publicly-held corporations" (Garrett 1956).

Reasons for and Against Shareholder Democracy

Several justifications are given for shareholder democracy. First, shareholders' efforts to increase their participation power are motivated by their desire to make corporate managers – officers and directors – more accountable (Fairfax 2008; Fairfax 2009; Smythe 2006). “Ultimately, many shareholders and their proponents believe that expanding shareholder democracy will lead to greater managerial accountability, thereby curbing managers' abuses of authority and ensuring that managers pay heed to shareholders' concerns” (Fairfax 2008).

A second reason relates to agency problems and the potential conflict of interests that may arise between shareholders and managers (Bebchuk 2007; Schwartz 1983). Although directors, conceived as agents of shareholders, are expected to act in alignment with shareholders' interests, they may in fact pursue their own interests in opposition to those of the shareholders. Shareholder democracy attempts to reduce this issue by involving shareholders more intimately in review, opinion, and decision-making. Third, there is a normative argument: it is argued that as the corporation's owners, shareholders are entitled to have greater participation in governance (Matheson and Nicolet 2019). Since shareholders are the owners of the corporation, they and not the directors are entitled to control the company.

Finally, shareholder democracy advocates argue that “shareholders are the sole residual claimants and, as such, are in the best position to exercise control for the good of all corporate constituents” (Hayden and Bodie 2010). Residual claimants, the last actors to receive payment from a corporation, are at the greatest risk. As a result of this risk, shareholder democracy advocates argue that shareholders should have greater control over the affairs of the corporate body.

Criticisms of shareholder democracy are mainly based on efficiency arguments. From an efficiency perspective, shareholder democracy is an inappropriate approach because, collectively, shareholders cannot manage the corporation

efficiently (Garrett 1956). Board primacy advocates argue that the successful management of corporations rests upon a clear and significant separation of powers between the shareholders as owners and the directors as managers (Garrett 1956). Other criticisms are based upon the possibility that some shareholders may be seeking to advance their own personal or political agendas (Fairfax 2008), or that shareholder empowerment benefits some shareholders more than others (Fairfax 2008), or that the interests of some shareholders – such as hedge funds – are opposed to the interests of the corporation's stakeholders more broadly (Fairfax 2008), or that “activist shareholders with only short-term interests may seek, and bring about, substantial changes that harm the prospects of some of the corporation's long-term goals” (Matheson and Nicolet 2019).

Strategic Focuses of Shareholder Democracy Advocates

Shareholder democracy is promoted through various strategies designed to give shareholders more power and control. Shareholder democracy first has focused on shareholders' voting power (Fairfax 2008; Fairfax 2009; Feis 1976). Enhancing shareholders' voting power increases the authority of this corporate body vis-à-vis the corporation (Fairfax 2009). Shareholder democracy seeks to enhance shareholder's voting power by reducing corporate management's control of the proxy machinery – the management's power to recommend candidates for nomination to the board and its relationships with significant shareholders who will delegate their voting rights or support the management's recommendations (Fairfax 2008; Fairfax 2009; Garrett 1956; Matheson and Nicolet 2019). “It has been asserted that the proxy statement is not the exclusive property of the management, and that those who challenge the management should have the right to include their independent nominations for directors in the management's proxy statement” (Garrett 1956).

Another way to enhance shareholders' voting power and improve shareholder democracy is by

establishing a system of annual elections rather than a system of staggered boards (Bebchuk 2007; Fairfax 2008). Shareholder democracy advocates view staggered/classified boards “as an entrenchment device that makes it difficult to replace the entire board in a single year” (Matheson and Nicolet 2019). Another way to enhance voting rights is to establish a majority voting regime instead of a plurality system (Fairfax 2008; Matheson and Nicolet 2019). Finally, voting power can be increased by the elimination of supermajority voting rules and the separation of the positions of the CEO and the chair of the board (Fairfax 2008).

A second strategy of shareholder democracy advocates has focused on shareholder advisory resolutions. These resolutions allow shareholders to submit proposals for action at a general meeting of shareholders (Fischel 1982; Garrett 1956; Matheson and Nicolet 2019). “This shareholder proposal process represents one of the only formal mechanisms available for shareholders not only to initiate dialogue, but also to potentially initiate corporate programs or policies on a given issue. As such, that process represents a critical component of shareholder activism” (Fairfax 2008).

Other strategies advanced by shareholder democracy proponents are (1) say-on-pay rules, which allow shareholders to have a say and monitor managerial pay within the corporation (Hayden and Bodie 2010; Matheson and Nicolet 2019); (2) derivative suits, “whereby shareholders could assert a claim against the managers for improper conduct” (Schwartz 1983); (3) shareholder advisory committees, where shareholders would have the opportunity, at a minimum, to receive information from corporate managers and provide feedback (Matheson and Nicolet 2019); (4) stock ownership consolidation in institutional investors, giving shareholders financial credibility and incentives to play a more active role in the corporation (Matheson and Nicolet 2019); and (5) proxy advisory firms, which “provide research and recommendations as to how institutional investors should vote their shares in publicly held companies” (Matheson and Nicolet 2019).

Summary

Shareholder democracy, an off-shoot of the “shareholder primacy” approach to corporate governance, attempts to give shareholders more power and a more active role in the management and decision-making of the corporation. Shareholder democracy is a contested concept, and various strategies have been proposed to implement the idea. These strategies include enhancing shareholders’ voting power, strengthening shareholder advisory resolutions, allowing derivative suits and stock ownership consolidation in institutional investors, and creating say-on-pay rules, shareholder advisory committees, and proxy advisory firms. Shareholder democracy, its advocates argue, is necessary because shareholders are the corporation’s residual claimants and because it increases the accountability of corporate managers and reduces agency problems between shareholders and managers.

[Corporate Engagement](#); [Shareholder Activism](#)

Definition

Shareholder engagement is the sub-class of shareholder activism, defined as a way for the shareholders to communicate and discuss their perspectives, concerns and ideas with their management, especially the board of directors and executive managers. Shareholders aim to have dialogues with the company, especially with the board of directors, who will receive constructive feedback on how to make improvements on the performance of the company. It also aims to ensure that the investment they made in the companies have an adequate and proper corporate governance and management mechanism. Ultimately, it focuses on bringing the attention of the board of directors and the management team to company changes in the near future. The person who attempts to use her/his shareholder rights of a public limited company (plc) to engage within the corporation's management is called *Shareholder Activist*. These shareholder activists believe a company's management can be improved by their engagements. They are not attempting to sell their share ownerships if they are not satisfied with the performance and management of the

company but rather attempt to gain control of the company and replace management or force a major change for the company. The behaviour of shareholders attempting to influence the management of a corporate by exercising their shareholder rights as partial owners are also well-known as Shareholder Activism. In particular, shareholder engagement is critical to institutional investors who hold shares on behalf of hundreds and millions of individuals and organisational entities, and they have a fiduciary duty to ensure that their holdings are in the best interests of the underlying investors.

Introduction

Forms of Shareholder Engagement

The forms of shareholder engagement between shareholders/shareholder activists and management team include annual general meetings, investor meetings, one-to-one dialogue meetings, shareholder voting, shareholder proposals, shareholder written consent, shareholder proxy statements, shareholder campaigns, discussions in the annual report, presentation of a corporate social responsibility report, announcements on the company website. In many circumstances, shareholder engagement begins with submitting a proposal by a shareholder representative. According to Institutional Shareholder Services (ISS) research, shareholder proposals had a 10% growth from 2012 to 2013 (ISS 2013). Issues like board members/chairman/leader elections, political lobbying and board components are commonly debated in shareholder proposals. The annual general meetings, investor meetings and one-to-one dialogue meetings are very popular in practice. Under the regulation Fair Disclosure (FD) of the Securities and Exchange Commission (SEC), corporates are required to be prepared in advance, and specific topics are selected for discussion purposes, provide fair and transparent disclosure of information, and enhance prohibitions against insider trading. There is a recent trend of shareholders demanding personal interaction with directors rather than just the investor relations officer (IRO) or members of

the management team. The one-to-one meetings reflect a new era in corporate governance. In some circumstances, offensive tactics (e.g., media channels, lawsuits/litigation threats) might force more pressure or a conversation for changes.

Shareholder Engagement Discussions

The communication topics are much diversified, and some of the major issues addressed by the shareholder activists include but are not limited to environmental, social, and governance (ESG) issues/corporate social responsibility (CSR) issues (O'Rourke 2003), corporate strategies, climate changes, divestment requests, risk management, executive compensation, profit distribution to the internal culture and business model of a company, board diversity. These topics are aimed at bringing the attention of the board of directors and the management team for a change in the near future. These shareholder activists believe a company's management can be improved by their engagements, and currently the management team did not do a good job. These shareholder activists are not attempting to sell their ownerships but rather attempt to gain control of the company and replace management or force a major change for the company. The behaviour of shareholders attempting to influence the management of a corporate by exercising their shareholder rights as partial owners are also well-known as *Shareholder Activism*. According to the Harvard Law Review (Harvard 2019), 2018 was a record year for shareholder activism. A record amount of capital of \$65 billion was deployed in new activist campaigns, which equals 30% over the average amount deployed from 2015 to 2017. The shareholder activist campaigns in 2018 held 60% in US companies, 25% targeted European companies, and approximately 10% targeted Asia-Pacific companies. Overall, the statistics overstate the success of shareholder activism.

Shareholder Engagement Process

Direct shareholder engagement is unlikely to be accessible to all shareholders. Hence, the engagement process starts with thoughtful preparations to ensure an effective and efficient dialogue. As a corporate, it is aimed to assess shareholder

ownership first and target specific shareholder representatives. Secondly, it is necessary to draw an effective shareholder policy to communicate successfully with shareholders. One of the corporate governance practices is to establish a shareholder engagement policy, which outlines formal guidance for companies to interact and communicate with shareholders. The shareholder engagement policy aims to facilitate effective communication between shareholders, boards and managers. Board members and managers can also find the relevant guidelines for best dealing with activist shareholders. Within the shareholder engagement policy, both parties could engage by following the interaction methods and types of discussion topics. Many corporations also consult a third party to help establish these parameters. As opposed to responding to ad hoc shareholder demands, a proactive, documented approach is becoming more common among corporations that engage with their shareholders. In addition, there is no standard shareholder engagement frequency. It depends on the nature of the demands and the board's preference. Some organizations' only communication is via proxy disclosures and press releases, while others prefer more frequent and proactive engagement of shareholders. However, it is commonly believed that increasing engagement frequency can improve the efficiency of corporate governance and management.

According to the survey of National Association of Corporate Directors (NACD 2018), over 20% of listed companies were approached by activist shareholders in the years 2015–2016. The statistics also showed that over 50% of the boards of listed companies have designated plans to respond to activist investors. Boards of small-cap companies indicated that they faced pressure from activist shareholders more often than large-cap companies (NACD 2018). As indicated by 44% of the responses of small-cap companies, they were more likely to assign a board director to meet with institutional investors in person at least once a year (NACD 2018). But, in fact, only small numbers of small-cap companies established a protocol for addressing shareholder inquiries and pressures.

Summary

Although it has become more common, organisations still have many questions about how to begin shareholder engagement, how frequently this engagement should be made, who should be responsible for it, and what discussion topics should be involved. Based on the statement of Deloitte (2013), boards that have strategically increased shareholder engagement have found it provides a good source of communication from shareholders directly. Southwood (2003) researched four case studies of shareholder engagement on issues of socially responsible investment and debated the conflicts of interest between shareholder power and sustainable business performance. He explained that the decisive long-term factor for sustainable business performance is the major rationale for shareholder engagement rather than the power of shareholders in enforcement. Hoepner et al. (2018) first concluded the truthfulness of whether shareholder engagement on ESG issues can benefit shareholders by reducing firms' downside risk with empirical evidence. Shareholder engagement activities will likely continue worldwide. Recent regulatory and corporate governance trends show that shareholder engagement has become very important in maximizing the shareholder relationship with its management. The impact of those relationships could have material consequences for both sides. A proactive and well-planned shareholder engagement strategy can be an effective tool to help foster relationships, enhance transparency, and hear from shareholders firsthand. Properly planned and executed shareholder engagement can benefit the management board and organisation. Gifford (2010) found that a strong business case and the values of the managers of investee companies are the most important contributors to shareholder salience.

However, it needs to be clarified that what the key rationales for the activity of shareholder engagement are; what channels of ESG engagement can create value for shareholders for the long-term purpose. It is reckoned that institutional investor engagement on ESG issues has paid extraordinarily widespread throughout the

financial markets in the world. Some scholars have discussed that the trend is caused by the growing public interest in ESG/CSR topics, the growing size of institutional shareholdings, low passing rate for shareholder proxy proposals (e.g., Gillan and Starks 2007; Grewal et al. 2016). Given the growth of the institutional shareholder's engagement on ESG issues, we still need more insights into understanding whether ESG-related engagement can create value and reduce shareholder risk.

[Shareholder primacy](#); [Shareholder Wealth Maximization \(SWM\)](#)

Definition

Shareholder model holds that the primary goal of commercial companies is to maximize shareholder wealth, namely, the company should be run for shareholder interests. Most people in the Anglo-American legal sphere see it as the primary corporate purpose, especially under the prevalent thought that “an organization should have a single valued objective” (Jensen 2001, p. 10). According to the neoclassical economics, shareholders are regarded as residual proprietary claimants for the income stream after all fixed claims are met. Consequently, it is argued that shareholders' interests can be aligned with the interests of the company, and thereby maximizing their interests would be

equated to maximizing corporate interests as a whole. The aggregate social welfare is also seen enhanced when shareholder value is increased. The board of directors and their delegates of daily management, executive officers, are as a result expected to serve for shareholder value. Providing better employee welfare, improving customer services, and contributing more to communities, among other things, are considered improper for managers to pursue unless these activities can serve as a means to maximize shareholder value in due course. By the same token, when conflicts arise between shareholders and non-shareholders, directors and managers are only required to address the interests of the former and to take actions to produce the highest possible returns for them even at the expense of the latter.

Overview

Companies are economic entities which should “strive to maximise value for shareholders,” and profit maximization thereby become the baseline goal for directors and executives of the company (Macey 2008, p. 2). When asked, “who owns the large public companies,” most senior managers of companies in the United States (US) answered it was shareholders (Macey 2008, p. 4). Similarly, according to a survey of course syllabi of US law schools, many faculties to this day still believe the focus on shareholders' financial returns is *settled law* (West 2011, p. 18). When those law or business students grow up and become corporate executives, they will undoubtedly view the corporate objective – namely, their main responsibility – as serving shareholder interests in all circumstances. Managing companies for purposes other than shareholder wealth maximization is as a result seen as unethical at best and illegitimate at worst. It is not surprising then when Professors Hansmann and Kraakman (2001, p. 439) claimed “[t]here is no longer any serious competitor to the view that corporate law should principally strive to increase long-term shareholder value,” or when Milton Friedman (1970, p. 33) asserted:

In a free enterprise, private-property system, a corporate executive is an employee of the owners of the business. He has a direct responsibility to his employers. That responsibility is to conduct the business in accordance with their desires, which generally will be to make as much money as possible while conforming to the basic rules of society.

In *Dodge v Ford Motor Corp* (1919) 170 NW 684 (US), often cited by shareholder primacists as the classic case for supporting shareholders' superior position, the Michigan Supreme Court held: "[t]he ultimate objective of companies as currently enshrined in law – i.e., to generate maximum value for shareholders – is in principle the best means also of securing overall prosperity and welfare" (Stout 2008, p. 167). More recently, Chancellor Leo Strine of the Delaware Chancery Court also wrote: "the corporate law requires directors, as a matter of their duty of loyalty, to pursue a good faith strategy to maximize profits for the stockholders" (Strine 2012, p. 155).

Although pivotal contribution from various corporate constituents such as employees, suppliers, and communities should not be ignored as regards the survival and prosperity of a company, taking their interests into account is a means for facilitating the end of maximizing shareholder wealth in the eyes of most people including the general public, business professionals, corporate lawyers, and even policy makers. This point is well exemplified by the so-called "enlightened shareholder value" approach in section 172(1) of the *Companies Act 2006* of the United Kingdom (UK). As Professor Davies argues, non-shareholder interests would not be taken into consideration unless "it is desirable to do so in order to promote the success of the company for the benefit of its members" (Davies and Worthington 2012, p. 542). Logically, it might not be unacceptable under certain circumstances to impair non-shareholders' interests for the sake of shareholder primacy.

Shareholder model as a corporate objective and norm (Posner 1997) of corporate governance is regarded as the fundamental view of modern corporate law scholarship (Smith 1997, p. 278). Even opponents of this approach concede its prevalence and dominance (e.g., Greenfield 2007). The most

direct impact of shareholder model is to require directors of board and corporate officers to strive for the highest possible shareholder profits; any behavior that is inconsistent with shareholder model is subsequently considered as *corporate deviance* (Macey 2008, p. 2). Basically, such an objective and governance norm determine that company law and good corporate governance practice should endeavor to design a system which on the one hand centers on shareholders' interests and on the other incentivize those who run the company to make as much profit as possible by aligning their interests with shareholders'.

Problems of Shareholder Model

Although agency theory (Jensen and Meckling 1976; Alchian and Demsetz 1972) has replaced traditional proprietorship theory (i.e., based on the concept of ownership) and has been generally regarded as the theoretical basis for shareholder model since the 1970s, the principal-agent model is indeed problematic. There are no explicit or implicit contracts between directors/managers and shareholders, and the former are elected and employed by the company instead of the latter, owing duties to the company in most circumstances. Issues such as separate legal personality and extensive board authority, including distributing dividends, cannot be explained by agency theory (Yan 2015). Suffice it to say here, the economic terms "principal" and "agent" do not bear the exact same meaning as their juridical counterparts; moreover agency theory fails to provide a rationale for the *sui generis* power or autonomy of the board.

Since the separation of control from ownership in modern large companies, shareholders no longer operate the business in person or take direct control of the company. Accordingly, is it meaningful to contend the agent nature of directors where shareholders as "principals" have little power to order or instruct their agents? Along with the changing nature of the ownership, relinquishing control rights by shareholders is seen to enhance efficiency by authorizing directors to manage companies for better return on their

investment (Blair 1995). In this regard, it is necessary to grant directors independent positions and unrestrained power to make corporate decisions while only subject to the most fundamental principles, such as fiduciary duties. If shareholders are allowed to constantly interfere with the management, efficiency would be substantially compromised. The “empowerment of centralized management” is one vital element to ensure the effectiveness of widely held public companies in terms of the significance of “business decisions with the speed and efficiency” (Strine 2006, pp. 1762–64). As in the traditional principal-agent relationship, directors as agents need decision-making power to run the company; they must obtain at least some discretion. Just as Professor Bebchuk (2006) pointed out, the power of the board in the United States is due to insulating boards from shareholder intervention more than the separation of control from ownership. Otherwise, it will be pointless to elect directors to run companies in the event that every decision is required to be made by, or negotiated with, shareholders as the so-called principals.

Besides, shareholder wealth maximization means, as the term itself suggests, generating the highest possible returns for shareholders, which mainly encompasses maximizing the value of shares of the company and the dividends to shareholders. In practice, it would be simplified into one assignment for directors and managers – that is, to maximize the share price for shareholders in order to secure their highest possible utility from the investment. The emphasis on shareholder model gives rise to increased risks of short-termism. Directors and their delegated managers are probably forced to adopt short-term strategies in order to boost share prices to satisfy shareholders. Particularly when their personal interest is closely tied to corporate financial performance measured by share price, short-termism will be difficult to avoid. Management may subsequently have strong inducement to manipulate the share price in order to get larger performance-based payment and the like. High trading frequency is a typical example of the lopsided focus on immediate profit from the fluctuations in the stock markets. Empirical studies clearly show that the average holding period of shares has significantly

decreased in recent decades. It is not infrequent for certain institutional investors to use a price index or computer program to complete a stock transaction without getting any details of investee companies. Directors would therefore be under pressure to adopt strategies to satisfy shareholders’ appetites.

The fact that companies are not able to succeed or achieve business goals in the absence of various non-shareholding stakeholders’ contributions cannot be ignored either. Apart from shareholders, other corporate stakeholders’ investments such as credits provided by creditors, labor and know-how provided by employees, services and products provided by suppliers, and infrastructure provided by governments are indispensable (Blair 1995). More importantly, these non-shareholding stakeholders become increasingly more essential in the survival and success of modern companies, while the importance of shareholders is constantly decreasing. For example, the role of equity issuance and physical capital in investment “is much less important than it was” in modern public companies at present (Kay 2012). Especially after adopting diversified and balanced portfolios, investors/shareholders become less concerned about the success of any particular company than her overall portfolio. Meanwhile, from time to time, it is likely for a shareholder to wish one of her investing companies to fail in order to obtain higher aggregated proceeds from the portfolio.

At the same time, the interests of non-shareholding stakeholders can also be affected by company’s performance (Blair and Stout 2006). If a company is badly run or becomes insolvent, creditors may not get back the interest along with the principal and employees may be made redundant. They have an interest in the company and cannot obtain enough protection by the incomplete contract due to the unbalancing bargaining power, informational asymmetry, and bounded rationality. On the grounds that the liability of shareholders would not exceed the initial investment, around some critical point such as the vicinity of corporate insolvency, shareholders are likely to take excessive risks. There is severe potential of externalization since shareholders are able to “reap all of the benefits of risky activity but do not bear all of the

cost” (Easterbrook and Fischel 1991, pp. 49–50). Worse, in the event that shareholders have possibly no chance to get anything, they will have much stronger preference for high-risk activities, especially when they lose the incentive to increase any margin since their so-called residual claim has gone under water in this setting (Easterbrook and Fischel 1991, p. 69). Moreover, the empty voting facilitated by modern financial and hedging techniques may further exacerbate such negative externalization.

Many problems occur when the shareholder model serves as the corporate objective – that is to say the primary goal for those who run the company should be shareholder wealth maximization. These problems become especially prominent after the corporate scandals and financial crisis in the beginning of the century. At best, it may not lead to the best corporate governance practice, and at worst it may provide the wrong emphasis on company law (Yan 2017). Both the theoretical foundation and the economic rationale for the shareholder model can be questioned. The problems in the context of shareholder wealth maximization, inter alia, short-termism, and externalization also warrant a serious re-consideration of the current shareholder-centered model. And we cannot solely rely upon external law to protect stakeholders and control negative externalities (Yan 2017).

Summary

The rationale claimed by shareholder primacists can be challenged and therefore may not be as valid as expected. On the other side, the pressure to pursue immediate profits or externalize costs may be released if shareholder model is replaced by a broader purpose. Meanwhile, other important values including fairness and justice can also be better preserved in the context of a broader corporate objective. As a result, it is time to reconsider the corporate objective in order to address the regulatory gap and functional limitation of external measures regarding the control of short-termism and externalization.

Definition

A shareholder resolution is a form of shareholder activism through which shareholders make a proposal to a company regarding a particular issue that they need the firm should address. This proposal should be voted in the shareholder general meeting. If the proposal passes, it serves as an advice to the board of directors in setting the strategy and management of the company. Activist shareholders seek to influence managers to change the strategic priorities and the behavior of the firm. Lately, activist shareholders have been paying greater attention to corporate social responsibility (CSR). This is demonstrated by the significant increase in the number of resolutions about social, environmental, and corporate governance aspects since the 1970s. By submitting a resolution covering CSR topics, shareholders try to promote and incentivize CSR practices by pressing managers and making them aware of their demands. Nowadays, shareholder resolutions on CSR are mostly common in Anglo-Saxon countries, particularly the United States (US), where the protection of shareholder rights is higher. In this country, the Securities and Exchange Commission (SEC) Rule 14a-8 regulates the process of submitting a resolution. Companies must respond to all shareholder resolutions by choosing among three options: (i) Managers can omit a proposal on legal grounds before the general meeting, (ii) the proposal can be included in the proxy statement to be voted in the general meeting, and (iii) managers can engage with the proponents to negotiate an agreed withdrawal prior to the general meeting.

Introduction

A shareholder resolution is a proposal that a shareholder or a group of shareholders make to the board of directors of public companies. By means of a resolution, shareholders show their dissatisfaction with how the firms are being managed and try to use their power to influence the way in which managers are running the company.

The filling of a shareholder resolution is a type of shareholder activism. Activist shareholders have several mechanisms at their disposal, which may be classified according to the frequency of their use, as well as to their privacy (Yamahaki and Frinas 2016). Specifically, a shareholder resolution is an extraordinary and public form of shareholder activism. It is the most relevant form through which shareholders exert direct pressure on companies. Shareholder resolutions are particularly common in countries with an Anglo-Saxon corporate governance system.

The filling of resolutions has become an important mechanism through which shareholders and investors try to foster CSR practices in their firms. Activist shareholders fill resolutions to challenge the legitimacy of the firm's behavior and the way in which it is currently managed. At the same time, they also try to improve the corporate social performance of their firms. Resolutions may cover a diverse set of policies and topics related to corporate governance, as well as social and environmental concerns. Nonetheless, there are specific topics that are salient within each field. For instance, social resolutions usually focus on labor and human rights, international operations, product responsibility, or healthcare. Within the environmental area, climate change (e.g., GHG emissions, energy) and animal protection highlight among other issues. Finally, corporate governance-related resolutions are mainly concerned with transparency and external reporting, compensation, and diversity in the board of directors. Corporate governance resolutions are usually more common than social and environmental ones. Shareholder resolutions seek to indicate the investors' concerns and to raise managers' awareness about these issues by suggesting the need for a change and solve them (David et al. 2007). In so doing, activist shareholders try to pressure firms to engage in CSR activities (O'Rourke 2003).

Some companies are more prone to be subject to shareholder CSR-related resolutions than others. Investors target firms with low CSR performance to signal the ineffectiveness of managers in improving the social responsibility of the firm (David et al. 2007). Shareholders also

focus on large companies because they are more visible and operate in more different environments; hence, they are more likely to suffer from social and environmental issues that must be addressed (Eding and Scholtens 2017; Rojas et al. 2009). Additionally, the presence of responsible shareholders in the ownership structure of a firm is related to its likelihood of receiving a CSR proposal (Eding and Scholtens 2017).

Once a firm receives a resolution, there are three possible outcomes: the company can try to omit the resolution on adequate grounds, shareholders may decide to withdraw it before being voted, or the resolution can be included in the annual proxy statement to be subject to voting in the annual general meeting. Shareholder resolutions are nonbinding recommendations. Those that pass are only advisory; hence, they may not be effectively implemented. However, regardless of the result, shareholder resolutions are useful mechanisms to raise awareness about CSR issues because they can have an internal and an external impact eventually. Shareholder resolutions help to increase the attention of managers and society about social and environmental problems. By means of being included in the annual proxy statement, these issues are made known to other investors and stakeholders of the firm, thereby increasing the pressure on managers. Additionally, some resolutions reach the general public because, if they are too relevant, they may be covered by the media. It is also noteworthy that a resolution may have a spillover effect on firms operating in the same industry. If these companies observe that industry peers receive a resolution, they might proactively adjust their behavior before being subject to one themselves.

Historical Evolution and Current Stage

The history of shareholder resolutions dates back to 1942. In that year, the Securities and Exchange Commission (SEC) allowed US shareholders to fill proposals to their firms through resolutions for the first time. However, the SEC prohibited the inclusion of social policy issues in the proxy statement on grounds of the "proper subject"

test, included in the rule 14a-8 of the Securities Exchange Act in 1948 (Proffitt and Spicer 2006). This situation changed in 1969, when a court authorized a group of activist shareholders of Dow Chemical, known as the Medical Committee for Human Rights, to present a resolution asking the firm to stop producing napalm, which was being used in the war of Vietnam (Ryan 1988). This moment represented the starting point of the submission of CSR-related shareholder resolutions. The Dow Chemical case led to the revision and adjustment of the “proper subject” test in 1976. This modification officially permitted the inclusion of social and environmental issues in the proxy statement, although other CSR-related resolutions had already been filled since the Dow Chemical milestone (Rojas et al. 2009).

During the 1970s, religious associations were the predominant group of investors filling CSR resolutions. Religious investor groups were pioneers in submitting social proposal because they had a moral motivation and a long-term perspective (Proffitt and Spicer 2006). Several organizations that grouped and organized religious investors appeared in that decade to help them in the process of filling resolutions. The Interfaith Center on Corporate Responsibility (ICCR) founded in 1971 is highlighted among the rest, and it still exists today. Despite being a key precursor, shareholder resolutions filled by religious investors in the 1970s received little attention as these groups were small. It was not until the 1980s that the relevance of CSR resolutions increased as other investors followed the lead of religious groups. In this decade, pension funds, institutional investors, and NGOs started to make CSR proposals through resolutions (Gillan and Starks 2007; Proffitt and Spicer 2006; Sjöström 2008). These investors often collaborated with religious groups, and they jointly sponsored resolutions on CSR (Dunn 2013).

Nowadays, resolutions are a common practice of CSR activist shareholders, and more social issues are being included in proxy statements. Shareholders that owned significant stakes in companies are paying increasing attention to social and environmental problems and urging managers to address them (Proffitt and Spicer

2006). Around 1,000 resolutions related to social and environmental issues were filled in US listed companies between 2014 and 2016 (SIF Foundation 2016). Some large well-known companies have received these resolutions, such as Home Depot, Cisco, Microsoft, Google, or Yahoo (Guay et al. 2004; Sjöström 2010). Religious groups are still relevant players in organizing the filling of resolutions. As a matter of fact, ICCR is one of the most important associations of activist shareholders, and it tracks the filling of CSR resolutions in United States. This organization has around 300 members with a total portfolio of \$100 billion (Goodman et al. 2014).

The Process and Outcomes of Shareholder Resolutions

Filling shareholder resolutions is a common practice in Anglo-Saxon states. By allowing shareholders to make proposals and to indicate deviance from what they consider an adequate running of their firms, it shows a high level of shareholder protection in countries with a common law corporate governance system. Among these countries, United States is the most active. The SEC Rule 14a-8 regulates the process of filling shareholder resolutions. The resolution should comprise a 500-word proposal. An investor needs to own \$2,000 in shares during at least 1 year to fill a resolution. Social or environmental resolutions are normally co-sponsored by several shareholders with the same objective. Activist investors usually lobby and form coalitions to increase the relevance and impact of their proposals (Rojas et al. 2009). This is important given that a resolution needs to be firmly supported to succeed. The practice of joining other investors when submitting a proposal is especially common among small shareholders. Several organizations, such as the above-mentioned ICCR, help shareholders to organize, share information, and coordinate resolutions. Activist shareholders also engage with other stakeholders, beyond other investors, to increase the social legitimacy of their proposal. For example, NGOs are important advisors when preparing

resolutions. Sometimes, they even pose their own resolutions by acquiring stakes in targeted firms or by engaging with shareholders that allow them to use their votes at general meetings (Guay et al. 2004). They try to promote change and push shareholder activism to address CSR issues.

Shareholders have to submit the resolutions at least 120 days before the release of the company's proxy statement. Firms must respond to all resolutions, regardless of the stake owned by the shareholders posing the proposal. Companies may choose between three responses: (i) omitting the resolution if it is not adequately presented, (ii) including the proposal in the proxy statement to be voted in the general meeting, or (iii) negotiating a withdrawal with the proponents before the general meeting. Each option indicates a different attitude, sensitivity, and responsiveness to shareholders' demands. Firms should study these options to decide their course of action because they have advantages and disadvantages (Rehbein et al. 2013).

The most strongly opposing and least responsive action that managers could take against a CSR resolution is formally omitting it with the permission of the SEC. This option is considered a failure because it clearly indicates that the company is not willing to consider or discuss the proposal. To get the permission, the company should prove that the resolution failed to satisfy the requirements for its submission or that it violated the proxy rules. SEC Rule 14a-8 also allows firms to legally omit resolutions if the subject matter is not considered proper, for example, if the issue is not relevant (it does not affect 5% of the corporate business) or if it is related to personal grievances. The company should start the omission process no later than 80 days before filling the proxy statement, and it should send the opposing declaration to the resolution proponents at least 30 days prior to the release of the statement. If the SEC agrees with the firm, the resolution may be excluded from the proxy statement. If the firm omits the resolution without permission, the SEC will proceed with enforcement actions against the company, such as the annulment of the general meeting.

If managers do not openly oppose the resolution or if they fail to get the SEC permission to

omit it, the proposal must be included in the proxy statement and be voted in the general meeting. The firm must send the proxy statement to all shareholders that are entitled to vote so that they know in advance the matters that will be discussed. Management makes recommendations on what shareholders should vote. Managers normally oppose most CSR resolutions and usually make a statement justifying their positions and advising shareholders to vote against them (Gillan and Starks 2007; Rehbein et al. 2013). Managers tend to oppose resolutions because (i) they do not want to see their power diminish or (ii) they consider that the proposals are unfeasible and/or detrimental for business (David et al. 2007; Rehbein et al. 2004). Therefore, most social and environmental proposal fails (Proffitt and Spicer 2006; Goodman et al. 2014). When this happens, the resolution could be resubmitted in the following year if it reached a minimum threshold of supporting votes (3% in its first year, 6% in its second, and 10% in its third and subsequent years). If the proposal is approved, it may not have any substantial effect on corporate behavior. Passed resolutions are non-binding and only serve as advice to the board of directors. So, if managers opposed the proposal, it may only lead to symbolic rather than substantial changes in corporate policies or actions, or it may even end up in not being considered at all.

Finally, managers can opt to settle a negotiated withdrawal with the resolution proponents before the annual general meeting. In contrast to the two prior alternatives, negotiating a withdrawal is a private way of handling a proposal (Semenova and Hassel 2019). This option is considered the most responsive corporate action because it initiates a dialogue between managers and proponents with the aim of negotiating a win-win agreement that satisfies both parties (Dunn 2013). Negotiating a withdrawal shows that the firm seriously considers the CSR resolution and that it is committed to comply and implement the proposal, at least to some extent (David et al. 2007). The negotiation process is then an attempt to adjust the competing interests of both parties to decide a common set of environmental and/or social issues that satisfy them. The firm is willing to accept

some of the terms of the proposal and adapt some changes, while activist shareholders may soften their demands. Although a settled withdrawal represents the most positive corporate response because it normally implies that some measures will be taken (David et al. 2007; Uysal 2014), it may sometimes represent a bad outcome. In some case, shareholders might decide to withdraw a resolution if they regard that they will not get the sufficient support in the general meeting (Rojas et al. 2009).

If the shareholders that propose the resolution are not satisfied with the firm's response (i.e., it was omitted or did not get enough votes), they still have a last call. In some cases, the shareholders that filled the resolution might regard that the issue addressed in the proposal is so important that they may not be willing to continue investing in the company and they could take the exit option: sell their stock and use their voice to publicly claim that this decision is driven by the reluctance of the firm to address a CSR proposal (Goodman et al. 2014). This situation is the most harmful because it has negative effects for both shareholders and firms. The former find that their demands have not been considered and feel betrayed, while the latter may see that its behavior is publicly scrutinized.

Companies analyze each resolution individually, and they decide the action that they will take considering the filler (Dunn 2013). Some proponents are more salient and powerful; hence, they may be able to negotiate a withdrawal. For instance, and in contrast to individual investors, mutual and public pension funds are more likely to get a commitment from the management to implement their proposals (Rojas et al. 2009). It is key for firms to take into account the demands of large activist shareholders to guarantee the access to financial resources (Dunn 2013). The topic of the resolution is also an important determinant of the firm's response. Negotiated withdrawals are more common when the resolution deals with an environmental or social issue than with corporate governance (Dunn 2013). For example, Rojas et al. (2009) found that proposals related to energy, human rights, international labor, or equal employment are more prone to be

negotiated and withdrawn. These authors also observed that these topics are usually covered in the resolutions filled by the most influential investors. Thus, there seems to be a topic-shareholder relationship that reinforces the success of the resolution. Finally, some firm characteristics are also important factors in explaining the likelihood of a resolution being negotiated. Companies with low levels of CSR performance (Clark and Crawford 2012) or that have been previously subject to a resolution (Reid and Toffel 2009) are more likely to negotiate a withdrawal.

Whatever the response and outcome, shareholder resolutions are useful mechanisms to increase awareness about CSR, because it helps to direct the attention of managers, other stakeholders, and other companies to environmental and social concerns, which may not be considered otherwise. Regarding management, CSR resolutions incentivize problem-solving decisions and foster an internal analysis of the firm (Proffitt and Spicer 2006). Managers must assess whether the issue is relevant for the company and decide whether or not to omit the resolution, recommend a negative vote, or negotiate a withdrawal. CSR resolutions may also have an impact on other stakeholders, beyond shareholders. Due to the public attention of some shareholder proposals, employees, customers, suppliers, or NGOs could take notice of the issue that the resolution addresses. Consequently, these stakeholders may contribute to exerting additional pressure on firms to adapt their policies (David et al. 2007; Rehbein et al. 2013). Finally, there could be a spillover effect to other firms (Rojas et al. 2009). Companies that operate in the industry of a firm being targeted with a resolution may have a proactive attitude. These companies could try to adapt their own behavior if they fear that they could be challenged with a similar resolution from their shareholders in the short term.

Shareholder Rights

Franca Ruhwedel

Rhine-Waal University of Applied Sciences,
Kamp-Lintfort, Germany

Description

Shareholders are the owners of a company, and as such, they are entitled to certain rights. Which explicit rights a shareholder has depends on the size of his equity stake and the jurisdiction in which the company is operating. Primary shareholder rights include the right to participate and vote at the company's general shareholder meetings and the managing directors' election. Shareholders have the right to obtain relevant and material information on the corporation on a timely and regular basis and are entitled to decide upon the distribution of a company's profit (World Bank, 2022).

In most countries, at least some of the shareholder rights are codified not in law but in “Codes of Corporate Governance,” which work according to a “comply or explain” mechanism. While small shareholders usually have limited incentive to

participate actively in supervising the management due to their small financial stake, institutional investors often play an active role in corporate governance and oversee the interests of the shareholders.

Following the growing attention on environmental, social, and governance issues (ESG), many shareholders no longer take only a financial interest in their company but expect that the company takes a responsible role in society.

Introduction

Any individual or legal entity that is a legal owner of equity shares of a company is a shareholder of the corporation. As shareholders own the company, they are entitled to certain rights, such as the right to influence company decisions by participating in general shareholder meetings of the company and the election of managing directors (OECD, 2015). In practice, how extensive the rights of shareholders are depends on the legal system the corporation is active in and the size of the equity stake of the individual shareholder. In some jurisdictions, different classes of shares grant different rights, for instance, a missing voting right can be compensated by a higher dividend.

The discussion about shareholder rights goes back to the beginnings of public companies, where the East India Company was the first to issue shares to the public as permanent capital in the seventeenth century in England. Following this example, previously family-owned companies started to acquire additional funding by acquiring further equity from outside shareholders. This development led to companies where ownership by the shareholders and control by the directors were separated (Hutton et al., 2017). As a result, the population of shareholders consists of potentially thousands of individuals who all pursue their personal interests. For practical reasons, the shareholders cannot make all decisions on the operating business themselves; this is why they delegate the management of corporate activities to a management team that is supposed to act on behalf and in the interest of

the shareholders. Still, certain significant decisions remain with the shareholders, such as the selection of the board members, amendments to the company's organic documents, or the approval of extraordinary transactions (OECD, 2015).

Berle and Means (1932) were the first to describe the potential conflict between shareholders and managers in their renowned publication "The modern corporation and private property." Ever since then, it has been under discussion how the rights of the owners of a company ("shareholder rights") could be protected from a potential self-interest of the company's managers doing the operating business. As Berle & Means state (Berle & Means, 1932, p. 121), "[H]ave we any justification for assuming that those in control of a modern corporation will also choose to operate it in the interests of their owners?" This problem has been widely discussed as the "Principal-Agent Problem" (Jensen & Meckling, 1976), and many publications have discussed how to prevent managers from acting in their self-interest (caused, for instance, by moral hazard, adverse selection, or consumption on the job). In general, strengthening the shareholder's rights could reduce the agency's problems. In jurisdictions with more concentrated ownership structures (common outside the US and UK), shareholder protection works not only against the self-interested behavior of managers but also against the misuse of large shareholders' power (Ruhwedel, 2003).

Shareholder Rights to Protect Shareholder's Interests

As shareholder rights are codified in the jurisdiction of each country individually, there are no uniform rights for all shareholders worldwide. In most countries, at least some of the shareholder rights are codified not in law but in "Codes of Corporate Governance." These codes work with a "comply or explain" mechanism that obliges the companies to either follow the code's rules or explain with which regulations they do not comply. Empirical evidence shows that the

introduction of such comply or explain codes benefits shareholders with increased company value (Fauver et al., 2017).

Shareholder protection laws in many jurisdictions worldwide have improved tremendously in the outgoing twentieth century, including rules such as the independence of board members, the introduction of audit committees, and the separation of the roles of chief executive officer and chairman (La Porta et al., 2000). Shareholder rights can be differentiated into *ex ante* rights and *ex post* rights. While *ex ante* rights include preemptive rights and qualified majorities for particular decisions, *ex post* rights allow the seeking of redress once rights have been violated (OECD, 2017).

Even though there is no globally accepted framework on shareholder rights, many countries follow the suggestions made by the OECD (2015) in their publication “G20/OECD Principles of Corporate Governance,” first published in 1999 and, since 2015, supported by the G20 states. The core values of the OECD framework are a high level of transparency, accountability, board oversight, and respect for the rights of shareholders and the role of key stakeholders. The OECD highlights that there is no single model of good corporate governance. An example is the two different models of board systems. In the case of a one-tier board, the shareholders elect outside directors to represent their interest in a single company board in which inside directors (such as the CEO) and outside directors are represented alike. In the case of a two-tier board, the shareholders elect their representatives to a supervisory board that controls the directors’ management as a separate body. In both cases, protection of shareholder rights is possible as long as the specific corporate governance rules and regulations enable this. As these general ideas are reflected in the comprehensive and fundamental publication by the OECD (2015), the principles can be found codified alike in the laws and Corporate Governance Codes of all countries with developed capital markets (World Bank, 2022).

However, some common elements underlie good corporate governance. Concerning the rights and equitable treatment of shareholders and

essential ownership functions, the OECD names the following (OECD, 2015, chapter II, shortened):

1. Shareholders should have the right to
 - Secure methods of ownership registration
 - Convey or transfer shares
 - Obtain relevant and material information on the corporation on a timely and regular basis
 - Participate and vote in general shareholder meetings
 - Elect and remove members of the board
 - Share in the profits of the corporation
2. Shareholders should be sufficiently informed about and have the right to approve or participate in decisions concerning fundamental corporate changes as follows:
 - Amendments to the statutes, articles of incorporation, or similar governing documents of the company
 - The authorization of additional shares
 - Extraordinary transactions
3. Shareholders should have the opportunity to participate effectively and vote in general shareholder meetings and should be informed of the rules, including voting procedures, that govern general shareholder meetings:
 - Sufficient and timely information shall be provided.
 - Processes and procedures for general shareholder meetings should allow for equitable treatment of all shareholders.
 - Shareholders should have the opportunity to ask questions to the board, place items on the agenda of general meetings, and propose resolutions.
 - Effective shareholder participation in key corporate governance decisions, such as the nomination and election of board members, should be facilitated. Shareholders should be able to make their views known on the remuneration of board members, and key executives, as applicable.
 - Shareholders should be able to vote in person or in absentia, and equal effect should be given to votes.
 - Impediments to cross-border voting should be eliminated.

4. Shareholders, including institutional shareholders, should be allowed to consult on issues concerning their fundamental shareholder rights.
5. All shareholders of the same series of a class should be treated equally. Capital structures and arrangements that enable certain shareholders to obtain a degree of influence or control disproportionate to their equity ownership should be disclosed.
 - Within any class series, all shares should carry the same rights. All investors should be able to obtain information about the rights attached to all series and classes of shares before they purchase. Any changes in economic or voting rights should be subject to approval by those classes of shares that are negatively affected.
 - The disclosure of capital structures and control arrangements should be required.
6. Related-party transactions should be approved and conducted to ensure proper management of conflict of interest and protect the interest of the company and its shareholders.
 - Conflicts of interest inherent in related-party transactions should be addressed.
 - Members of the board and key executives should be required to disclose to the board whether they, directly, indirectly, or on behalf of third parties, have a material interest in any transaction or matter directly affecting the corporation.
7. Minority shareholders should be protected from abusive actions by, or in the interest of, controlling shareholders acting directly or indirectly and should have adequate means of redress. In addition, abusive self-dealing should be prohibited.
8. Markets for corporate control should be allowed to function efficiently and transparently.
 - The rules and procedures governing the acquisition of corporate control in the capital markets and extraordinary transactions such as mergers, and sales of substantial portions of corporate assets, should be clearly articulated and disclosed so that investors understand their rights and recourse. Transactions should occur at transparent prices and under fair conditions

that protect the rights of all shareholders according to their class.

- Anti-takeover devices should not be used to shield management and the board from accountability.

Additional rights such as the approval or election of auditors, direct nomination of board members, the ability to pledge shares, the approval of distributions of profits, shareholder ability to vote on board members and key executive compensation, approval of material-related party transactions, and others have also been established in various jurisdictions (Swain, 2022). In most cases, these rights are still codified in law and not in the abovementioned corporate governance codes subject to “comply or explain.”

Some jurisdictions allow different share classes where each share class has specific rights (see no. 5 above). A typical example is the differentiation between common shares and preferred shares. Common shares grant all the rights described above. Preferred shares, on the other hand, do not entitle the shareholder to vote at the general shareholder meeting. However, this lack of voting right is compensated by a preferred dividend and preferred right in case of insolvency (Seligman, 1985). Investing in these kind of preferred shares might be interesting for small shareholders who are not interested or lack time and voting power to influence the decisions in the general shareholder meeting.

In some cases, certain classes of shares come with different voting rights, for example, A-shares with ten votes attached and B-shares with only one vote attached. Giving this kind of “superpower” to class A shareholders can be seen critically from a corporate governance perspective if not every potential investor has access to invest in these shares as they might be held by the founding family, for instance (Seligman, 1985).

Shareholder Activism

Empirical studies show that suitable corporate governance structures lead to better performance (McKinsey & Co., 2020). Therefore the

protection of shareholder rights is in the vital interest of all shareholders (Hoepner et al., 2022). The shareholder rights described above should generally protect shareholders from exploitation. Nevertheless, they are only of limited use in motivating small shareholders, in particular, to exercise their rights actively. The smaller the financial stake in the company, the less incentive there is to participate in the general shareholder meeting actively. It can be observed empirically that many shareholders do not use the right to vote and therefore do not exercise their shareholder rights (Hewitt, 2011).

The question arises: Who is able and willing to protect the rights of shareholders and use the rights they are given? In the USA, so-called Proxy Advisors have a long tradition of not only providing services to shareholders such as vote administration and execution but also giving recommendations on how to vote. However, yet again, small shareholders are usually unwilling to invest money to use the professional services offered by proxy advisors (Larcker et al., 2015).

Over the last years, it can be observed over the world that institutional investors tend to become more involved in corporate governance discussions and act on behalf of shareholders' interests. They act as "active investors" and get involved in various ways, for instance, by claiming supervisory board seats in the case of two-tier boards or taking over as external directors on one-tier boards. In addition, activist shareholders initiate changes in the composition of the management board and suggest improvements in corporate governance structures. They put pressure on the management, organize voting majorities, and have, in many cases worldwide, already initiated significant changes (Swain, 2022). Other areas in which active investors intervene are M&A-related topics or ESG issues. Active investors sometimes act "behind the scenes"; in other issues, they use the press to increase pressure or file litigations. In any case, they try to assemble other shareholders to organize voting majorities to be successful with their requests at the general shareholder meeting (Larcker et al., 2015).

There are many cases in which active investors had a positive contribution toward an

improvement of corporate governance (McKinsey & Co., 2020). Nevertheless, it must be taken into account that activist investors represent their personal interests, which are not necessarily in the interest of all shareholders (McNulty & Nordberg, 2016). An example of a self-interested behavior of a large shareholder could be a supplier relationship that is not structured at arm's length or an excessive withdrawal of dividends which hinders the company's future growth. Moreover, especially if the active investor has a relatively short investment horizon, it is conceivable that stakeholder interests might be neglected, and activities taken might instead favor short-term returns than long-term corporate success. Therefore, empirical results on the impact of shareholder activism on company performance do not point in a clear direction (Barros et al., 2021).

While, on the one hand, institutional investors often take an active role in corporate governance, the growing importance of index-tracking funds partly offsets this development and can lead to increased passivity of shareholders as a whole, on the other. Index-tracking funds hold significant stakes in many companies, but as they focus on cost-efficiency, they do not actively monitor the management (Barzuza et al., 2019). Besides, the market for passive funds is dominated by large investment companies, which hold significant stakes in many companies and therefore lead to a concentration of ownership (Cheffins, 2019).

Balance of Shareholder Rights and Stakeholder Rights

While discussing shareholder rights, one must consider that shareholders are not the only party taking an interest in the company. As part of the stakeholder theory, it has been discussed for decades whether the rights of stakeholders such as employees, the public, or suppliers should be considered as vital as the rights of shareholders (Freeman, 2001). In contrast to the stakeholder-oriented approach, the supporters of the shareholder value theory have focused solely on

maximizing the company value in the short run (Rappaport, 1999).

The focus on shareholder value has been criticized heavily over the last years as the idea of corporate purpose and the relevance of environmental, social, and corporate governance policies (ESG) has gained importance. The recognition that ESG policies play a vital role for companies these days (Hutton et al., 2017) is fostered by demanding customers who expect companies to act socially and sustainably. However, not only do customers put pressure on the companies but also there are several legislative initiatives like the EU Green Deal to ensure ESG-responsible business behavior. Recently besides the public, increasingly influential shareholders stress that they expect corporations to not only act in favor of increasing profit but also play an active and responsible role in society. A wake-up call in this sense was the 2020 annual letter by BlackRock CEO Larry Fink, entitled “A Fundamental Reshaping of Finance.” As BlackRock was long regarded as prototype of a purely shareholder value-oriented investor, their shift toward a demand for ESG-responsible behavior in their investment companies caused a mindset-change not only in companies where BlackRock had a stake. Nowadays, many institutional investors define explicit demands concerning ESG topics. If companies do not meet investors’ requirements in this regard, they risk the availability of capital and thus declining company values in the long term. On the other hand, engagement on environmental, social, and governance (ESG) issues can benefit shareholders by reducing firms’ downside risks (Hoepner et al., 2022).

Summary

Shareholder rights are codified in law, and in addition to that in “Codes of Corporate Governance,” in which following a “comply or explain” mechanism, the companies have to state if they do not comply with specific regulations. The rights of shareholders differ from country to country. Still, the rights stated in the OECD/G20 Principles of

Corporate Governance are widely accepted in most countries with developed capital markets. Fundamental shareholder rights include the right to participate and vote at the company’s general shareholder meetings and the managing directors’ election. In addition, shareholders have the right to obtain relevant and material information on the corporation on a timely and regular basis, and they are entitled to decide upon the distribution of a company’s profit.

Each shareholder is entitled to the codified rights and can vote in the annual shareholder meeting. As small shareholders have limited incentives to inform themselves and exercise their voting rights due to their small financial stake, shareholder rights are often not exercised in practice. At the same time, the growing importance of index tracking funds also has the effect that voting rights are not exercised. On the other hand, institutional investors often play an active role in corporate governance and carefully watch the shareholders’ interests. In the past, the shareholder value theory played a principal role, and the focus of shareholders was mainly on profit maximization. Following the growing attention on environmental, social, and governance issues (ESG), this has changed, and many shareholders no longer take only a financial interest in their company but also expect that the company takes a responsible role in society.

Shareholder Theory/ Shareholder Value

Maeve O'Connell¹ and Anne Marie Ward²

¹Technological University Dublin, Dublin, Ireland

²Ulster Business School, Ulster University, Newtownabbey, Northern Ireland

Synonyms

Shareholder primacy theory; Shareholder value creation; Shareholder value maximization; Shareholder wealth maximization; Shareholder-centric approach

Definition/Description

Shareholder theory states that the primary objective of management is to maximize shareholder

value. This objective ranks in front of the interests of other corporate stakeholders, such as employees, suppliers, customers, and society. Shareholder theory argues that shareholders are the ultimate owners of a corporate's assets, and thus, the priority for managers and boards is to protect and grow these assets for the benefit of shareholders. Shareholder theory assumes that shareholders value corporate assets with two measurable metrics, dividends and share price. Therefore, management should make decisions that maximize the combined value of dividends and share price increases. However, shareholder theory fails to consider that shareholders and corporates may have other objectives that are not based on financial performance. For example, as early as 1932, Berle and Means argued that corporations have a variety of purposes and interests including encouraging entrepreneurship, innovation, and building communities. This wider view is gaining more traction in recent decades as evidenced by an increased interest in ethical investment funds. This suggests that shareholders and potential shareholders are not only interested in financial gains but are also interested in corporates being socially responsible (Kyriakou 2018). Therefore shareholder value creation is important; however, it needs to be balanced with other stakeholders' interests. This is referred to as an enlightened approach to shareholder value maximization.

This entry outlines the origins of shareholder value theory, provides a rationale for prioritizing shareholder value theory, documents arguments for taking a wider view beyond shareholder value, and explains enlightened shareholder value.

The Origins of Shareholder Value Theory

The origin of shareholder value maximization as the primary objective of corporates was influenced by changes in the structure of businesses, the economic environment, and financialization of the markets. These are now outlined in brief.

Business structure and the economic environment: The roots of shareholder value theory can be

traced to the late eighteenth century when the capital investment required to finance innovative manufacturing businesses during the industrial revolution led to a change in the structure of businesses, from traditional small family-run corporates to large publicly owned corporates with dispersed shareholders and professional managers. This change in governance, called managerialism, led to new modes of coordinating enterprise, technology, and planning. From the 1970s, the focus on managerialism gave way to a growing focus on shareholder value maximization. The economic environment is considered to have contributed to this change in focus. The 1970s was a challenging time for US corporates as they experienced a decline in competitiveness due to the rise of foreign corporates. The result was decreases in their share prices. Questions were being asked about the performance of management in this era. The widespread reduction in the value of corporate stocks led to a focus by business leaders, policy makers, regulators, and politicians throughout the 1980s and 1990s on the role of the board and their duty and relationship to shareholders. In particular, agency theory, an economic theory that argues that humans are inherently self-serving, was deemed to provide an appropriate explanation for the poor performance of corporates. The view being that boards were taking decisions that benefited directors, not shareholders. This resulted in the widespread promotion of shareholder wealth maximization as the primary goal of corporates. Directors were not opposed to this approach as they believed that by focusing on wealth maximization, they could avoid their corporate being the target of a takeover bid. This reason was particularly pertinent in the 1980s as a wave of merger activity was sweeping through major stock markets. In addition to being a defense against takeover, a focus on wealth maximization also led to calls for the alignment of director and shareholder incentives. The result was a higher executive director pay that was typically linked to share price increases. This further motivated management to focus on shareholder wealth maximization. However, it is also argued to have fueled a focus on short-term gains that benefit transient investors and directors, to the

detriment of long-term shareholders and other stakeholders that are interested in the sustainability of the corporate (Clarke and Friedman 2016; Englander and Kaufman 2004).

Financialization: During the 1980s financial institutions became substantial investors in corporate shares. Financial institutions pursue wealth maximization as their primary investment objective. This increased attention from well-informed investors and led to pressure on directors to deliver high returns on their tangible assets. If high returns are not reported, then corporates faced the risk of being taken over and broken up. This shifted the priorities of corporates to cost-cutting, divestiture, outsourcing, and offshoring as managers did whatever was necessary to meet the earnings expectations of the market (Dallas 2017). Improvements in information technology in the 1980s and 1990s also resulted in easier access to information on corporates, increased interest from a wider range of investors and hence greater liquidity in the stock market. In particular, it enabled more trading by transient shareholders whose main focus is liquidating short-term abnormal gains. The shift in focus to reporting short-term gains is argued to conflict with the long-term sustainability of corporates.

The arguments for and against the pursuit of shareholder wealth maximization are now outlined in brief.

The Rationale for Prioritizing Shareholder Value

Four main arguments in support of the primacy of shareholders over other stakeholders are forwarded in the literature; the agency perspective, the control perspective, the residual claims perspective, and congruence with social wealth.

The agency perspective: The first view, the agency perspective, is that directors have a contractual obligation to prioritize shareholder value maximization over other stakeholder claims. Under agency theory the corporate is seen as a “nexus of contracts” (Alchian and Demsetz 1973). Shareholders are the owners. They are external to the corporate and hence cannot manage the

corporate. Therefore, shareholders hire agents (managing boards) to protect their interests and to run the corporate on their behalf (Jensen and Meckling 1976). To fulfill their contractual obligation, boards should take decisions that promote the long-term sustainability of the corporate. The traditional view is that long-term sustainability is synonymous with financial prowess. Therefore, the focus should be on financial decision-making that maximizes shareholder value in terms of dividend returns and increases in share price. This traditional view is captured by Friedman when he stated: “Few trends could so thoroughly undermine the foundations of our free society as the acceptance by corporate officials of a social responsibility other than to make as much money for their stockholders as possible” (Friedman 1970, p. 113). Friedman went on to explain that catering for multiple stakeholders with multiple objectives increases the risk of managerial mismanagement and may even conflict with shareholder wealth. Therefore, the role of the board is to manage, grow, and protect shareholder assets. This can be achieved by a focus on sustainable development.

Control: Under the control view, shareholders are the controlling influence and hence the most important stakeholder. Each share has voting rights and though shareholders transfer their control rights to the governing board to run the corporate on their behalf, they have influence over the board. They can attend annual general meetings and remove individual directors, and they can influence board decision-making through their voting rights at meetings. Therefore, though they have transferred operational decision-making control to the board, shareholders retain ultimate control. As a result, shareholders are the most important stakeholder, and the governing board, managers, and employees should act to maximize shareholder wealth. The maximization of shareholder wealth is achievable when long-term sustainability is achieved.

Residual claims: Shareholders provide funds to the corporate for investment. The corporate invests these funds in assets. Therefore, any assets purchased with shareholders’ funds are the property of the shareholders. However, under law, the

contractual rights of other claimants, such as employees and suppliers, rank in front of shareholders' contractual claims. This means that shareholders are only entitled to the residual value when the corporate is wound up after all other contractual claimants have been satisfied. Consequentially, shareholders bear more risk and hence have a greater interest in the corporate's long-term sustainability relative to other stakeholders. Each decision made by the board has a direct impact on shareholder wealth, whereas all other stakeholder claims are typically fixed. Therefore, governing boards should focus on maximizing equity shareholder wealth as this will ensure the long-term sustainability of the corporate.

Congruence with social wealth: A fourth argument in support of shareholder value maximization is that it has value for the wider society. When governing boards focus on shareholder wealth maximization, this results in benefits for other stakeholders. For example, to increase sales revenues, policies may be introduced that improve customer service or provide a wider product range. This will lead to additional profits for shareholders as customers return more often. However, it also benefits customers who experience higher quality service and have access to a wider range of products. Similarly, to reduce staff recruitment costs, a corporate might invest in staff training or introduce flexible working hours. This will cut costs due to lower staff turnover, lower sick rates, and improved productivity from happier workers. The changes are also beneficial for workers who increase their human capital by gaining new skills and can better manage their work-life balance. In addition, financial gains to shareholders will also have a societal impact as in modern developed economies, a majority of the population have investment in stock markets. This investment may be direct, through the purchase of shares, or indirect, through their pension funds. Thus a focus on shareholder value is argued to be beneficial for society at large. Politicians in several jurisdictions have equated the performance of the stock market with the interests of their voting public (Cioffi and Höpner 2006).

Why Take a Wider View Beyond Shareholder Value

As early as 1992, Michael Porter claimed that economic instability and insecurity results from a focus on shareholder value maximization. More recently Clarke (2015) argued that the relentless search for returns, regardless of the consequences, and the self-interest and irresponsibility embodied in the pursuit of shareholder value, was at the heart of corporate scandals, such as Enron and WorldCom in the early 2000s, and the reckless excesses leading to the global financial crisis of 2008. Moreover, government bailouts of banking corporations in the aftermath of the financial crisis, with the associated short- and long-term costs to taxpayers, indicate that an excessive focus on maximizing shareholder wealth not only damages shareholders but also has a negative impact on society.

Some opposing arguments for the rationale forwarded under agency theory, control, residual claims, and congruence with social welfare are now outlined.

Agency theory: Agency theory identifies that directors could be self-serving at the expense of shareholders and that this can have negative consequences for the long-run sustainability of a corporate. It argues that monitoring directors and incentive alignment that leads to decision-making that is congruent with shareholder value maximization should result in director decision-making that is consistent with shareholder value maximization. However, the empirical literature is inconclusive as to whether methods used to reduce agency, lead to better outcomes for shareholders (Pargendler 2016). There are plenty of examples of corporate failures despite clean audit reports by auditors, for example, Enron. In addition, it is claimed that techniques used to align board decision-making, for example, share options, have not curbed dysfunctional decision-making, for example, Nortel. It would seem that agency theory is an oversimplification of the complexity and heterogeneity of financial and corporate reality. Economics is not the only driver of human interactions; it is also shared by politics, ideologies, legal systems, social conventions, modes of

thought, etc. (Letza et al. 2008). Therefore, a focus on shareholder wealth is appealing for its simplicity but fails to take into account the complexity of the corporate world.

Control: While shareholders own shares in corporations, they are defined under law as separate legal entities. They exist separate to their aggregate members, with their own rights and duties that do not derive from the rights of their shareholders (Letza et al. 2008). Therefore, as distinct social entities, the directors' duty is to each distinct entity, not the aggregate shareholders.

Residual claims: Though shareholders are not guaranteed a return, they are not the only stakeholder to invest in corporations without a guaranteed return. Taxpayers, through government agencies, and employees, also invest in corporations without a guaranteed return. Government agencies provide infrastructure that corporations use and may even directly provide grants or subsidies to corporations. The return is tax revenues and societal gain. Employees make investments in "corporation-specific" human capital and unpaid hours of input with the expectation that they will reap returns (wages) from that corporation in the future. When the role is specialized, or the employee is older, their mobility is impaired and the potential loss in terms of future returns (wages) is greater. Employees cannot diversify their investment as easily as shareholders can. In addition, shareholders can exit at any time. This is not as easy for taxpayer investment or for some employees. Therefore, it could be argued that shareholders are not the key risk takers, as other stakeholders such as taxpayers and employees also face considerable risk. Indeed, their loss when a corporation fails may be even greater than shareholders' losses.

Congruence with social wealth: Pargendler (2016) suggests that there is little congruence between focusing on shareholder value and social wealth. They find that share price increases do not benefit society equally, that the wealthiest 10% of the population own 81% of the stock, whereas the bottom 80% of the population hold 9% of shares. Moreover, given this skewed concentration of ownership, shareholders have few incentives to act as stewards

for the public good. Thus, there is little overlap between the interests of shareholders and those of wider society. Pargendler's (2016) conclusion focused on the outcome of the pursuit of financial objectives, where the output is dividends and share price increases; however, there are other beneficial outcomes from corporate sustainability that benefit the wider stakeholder body. Recognition of these benefits has led to calls for an approach termed "enlightened shareholder value."

Enlightened Shareholder Value

Under shareholder value theory, the corporate is viewed as a body of shareholders with the board's duty to the shareholders. Shareholder value theory also assumes there is a single, common and uniform measure of shareholder value, dividends and share price increases, and that shareholders are only interested in financial returns. However, this may not be an appropriate assumption. As early as the 1970s, activist shareholders have submitted proposals on social issues at annual general meetings. This suggests that shareholders have interests other than financial returns and that by catering for other stakeholder interests, boards are in fact catering for shareholder interests. Moreover, furthering shareholder value is not mandated under corporate law (Stout 2012), and the law has imposed duties on boards to other stakeholders, such as to employees and suppliers. For example, in the UK (Companies Act 2006) and Ireland (Companies Act 2014), directors have a duty to promote the success of the corporate for the benefit of its shareholders while having regard to the interests of employees and to creditors generally, particularly in times of threatened insolvency. A stakeholder-orientated approach to governance is evident in continental Europe and Japan where shareholder value and stakeholder interests are not separate and isolated from each other but interdependent, mutually influential, and reciprocally supportive (Letza et al. 2008). More widely, investors in many markets reported that even where a primary duty to shareholders is accepted, this does not exclude engagement and action on sustainability issues (Sullivan et al. 2015). This

approach is referred to as the “enlightened shareholder value” approach.

The enlightened shareholder value approach focuses on long-term value creation and the interests of various stakeholders, in advancing shareholder value. Shareholder interests are predominant; however, the promotion of their interests does not require ignoring the interests of other groups deemed to be important to the success of the corporate. Boards are permitted to take different stakeholder interests into account if deemed to be congruent with long-term shareholder wealth maximization. It would be hard for boards to make decisions that treat the well-being of employees or the environment as the primary cause for action (unless based on other legal obligations under employment or environmental law). An enlightened approach does not extend to additional rights for stakeholders, nor does the approach prioritize other stakeholders at the expense of shareholders. However, it argues that all stakeholders benefit from a long-term view and hence the sustainability of the corporate. As with any corporate investment, investment in a corporate stakeholder group should earn a return for the whole corporate, and there is some tangential evidence to suggest that this is the case. For example, De Klerk et al. (2015) report higher share prices in corporates with higher levels of sustainability disclosures. Thus it would seem that sustainability and value maximization have the potential to be complementary undertakings that result in a virtuous circle in which “doing good” helps companies do well, and doing well provides the wherewithal to do more good (Martin et al. 2009). Policy makers also are promoting a more enlightened approach. There are increasing legal requirements on corporates to publish on social and environmental matters, for example, the EU Non-Financial Reporting Directive 2014/95/EU. In addition, stock exchanges have started to require their members to comply with Corporate Governance Codes that contain requirements on disclosures of social and environmental matters (KPMG 2017a).

A refocus to enlightened shareholder value is consistent with the growing numbers of institutional investors who include sustainability criteria and metrics when developing and

assessing portfolios of shares (Chen and Scholtens 2018; Miralles-Quiros et al. 2017; Sullivan et al. 2015). Even Michael Jensen, the champion of agency theory, has conceded that in order to maximize value, managers must not only satisfy but enlist the support of all corporate stakeholders (Jensen 2002).

Summary

Taking an enlightened shareholder value approach is not as clear cut as pursuing financial objectives that result in stronger financial ratios, higher dividends, and increases in share price. Setting non-financial objectives is difficult as there are measurement and reporting issues with limited guidance from policy makers. However, financial performance and sustainability are not divorced from each other. Share price is a vital indicator of corporate performance. It reflects the underlying value of the corporate, including potential future sustainability. Financial performance is important not only for shareholders but also for other stakeholders. For example, without financial sustainability, employees’ future income stream is at risk, suppliers’ future income stream is at risk, customers’ access to products is at risk, and the public cannot benefit from the infrastructure funded by tax and direct investment by corporates.

Conflict typically arises between shareholders and other stakeholders, not because of the pursuit of financial objectives, but due to agency issues, wherein self-serving boards make decisions that focus on short-term gains that put the long-term sustainability of the corporation at risk. This approach only benefits short-term transitional shareholders who trade for quick speculative gains. This behavior does not serve the interests of long-term shareholders, who are interested in the sustainability of the corporate. As a result of agency behavior, legislative and regulatory intervention is required to ensure corporations respond to the growing public demand, that they recognize their wider social and environmental responsibilities and avoid a singular focus on short-term financial shareholder wealth maximization.

Definition

“Sharing” as a concept predating long time ago is a form of exchange in human behavior and constitutes the most basic pattern of human economic behavior (Price 1975). In recent years, sharing has gained increased attention as a mode of consumption and even becomes more attractive than purchasing for some consumers, as its heightened importance as being a part of sustainable models of consumption has been emphasized in the accumulated body of extant research (Belk 2014; Hellwig et al. 2015). In this sense, there exist several distinct concepts that can be used interchangeably with sharing economy, such as peer-to-peer economy (Nielsen 2014), collaborative consumption (Botsman and Rogers 2010), social sharing (Benkler 2004), access economy (Rifkin 2000), and access of ownership (Bardhi and Eckhardt 2012). However, sharing can be defined as “people coordinating the acquisition and distribution of a source for a fee or other compensation,” which refers to both monetary and nonmonetary transactions (Belk 2014, p. 1597). Further, sharing also refers to “the consumption of goods and services through activities such as renting, swapping, or trading,” referring to distinct forms of sharing such as second-hand buying, donating, and borrowing (Hamari et al. 2016). Also, Botsman and Rogers (2010) described the concept of sharing as “systems of organized sharing, bartering, lending, trading, renting, gifting, and swapping.” Further, access of ownership refers to the sharing of goods or services for a limited time period via peer-to-peer sharing activities such as lending or renting among individuals (Bardhi and Eckhardt 2012).

In concurrence with the meaning of the concept, sharing business models enable people to share their own assets with other individuals in distinct and different stances. In this context, people could have access to use other individual's flats (e.g., Airbnb, CouchSurfing), cars and bicycles (e.g., Turo), clothes (e.g., Modacruz, Dolap.com), pet care (e.g., Rover), and taxi services (e.g., Uber). On the other hand, sharing economy platforms differ with regard to its purpose. While

some of them provides not-for-profit access-based consumption to the consumers for a temporary time period, enabling individuals to use them for free (e.g., Couchsurfing), others are stimulated by financial motives and rely heavily upon monetary compensations (e.g., Airbnb).

Introduction

With the development of Internet and information technologies, online platforms have been risen to the surface with an intent of encouraging user-generated content, sharing, and cooperation among the consumers. For instance, Wikipedia can be a good example for collaborative online encyclopedia, based upon the accumulated information sharing of individuals. Also, YouTube and Instagram could be given as great examples for content sharing platforms, as individuals share their own creative contents within the platform. Hence, the concept of sharing economy is stemmed from several technological developments which make the sharing activity of tangible and intangible goods and services easier for people.

In virtue of allowing individuals to share their goods or services via monetary or nonmonetary transactions, the phenomenon of sharing economy has changed the definition of “ownership” and “employment” (Belk 2014). In this sense, a new concept of “sharing rather than purchasing” has received a great deal of attention among today’s consumers considering its three major contributions to the economy (i.e., developing new revenue models), society (i.e., increasing social engagement among the individuals), and the environment (i.e., protecting the limited resources via cooperative consumption). The new concept has shifted the mindsets of consumers over recent decades and gained the heightened interest of entrepreneurs, governments, the media, and academic researchers. While traditional economic view support the certain premise that transfer of ownership takes place when people exchange of goods and services, the new sharing economy has suggested new forms of

exchanging goods and services such as “access over ownership,” consisting activities of borrowing, lending, and renting rather than purchasing and owning the goods and services (Botsman and Rogers 2010).

With respect to its economic influences, PwC has reported the five industries that take the major role in the context of sharing economy as travel, car sharing, staffing, music, and video streaming, generating \$15 billion in their global annual revenue but expecting a huge increase in their market share up to \$335 billion by 2025 (PwC 2016). On the other side, both corporations and individuals have started to assess the alternative of sharing as an environmentally friendly option and more profitable choice when purchasing goods and services. In this context, the sharing economy can be regarded as an umbrella concept incorporating the notion of “collaborative consumption,” which encourages the sharing and consumption of goods and services via online platforms and enables consumers to exploit less resources in concert with the sustainable development goals of the United Nations.

Key Issues

There exist four distinct aspects that would lead individuals to engage in the sharing-based economy. First, consumers may engage in sharing activities via online platforms, which are called “collaboration online.” In this form of activity, individuals create their own content with an aim of sharing their knowledge among the online users. For instance, consumers make transfer of knowledge via file sharing and share their own content with other consumers. Second, another aspect in the sharing economy is related to the concept of “social commerce,” which is a peer-to-peer cooperation that is mediated by social media via integrating both offline and online settings. In this form of commerce, users may highly involve in the exchange process by the help of social media and make their own contributions to the goods or products. Social commerce combines shopping and social interactions in both offline

and online platforms owing to taking opportunities of information technologies and social media.

Besides, the third aspect of sharing economy – “sharing online” – implies to the “access over ownership,” referring to the share of goods and services by means of information technologies. For example, collaborative consumption platforms (e.g., CouchSurfing, BlaBlaCar) can be regarded as a “sharing online” option of sharing-based economy, as individuals use online platforms to share their own houses or cars regardless of monetary or nonmonetary purposes. The fourth one includes the ideological considerations of sharing economy, which implies to the collective activities such as campaigns disseminated through the help of social media and open sources. For instance, users may generate mutual funds with an aim of helping needy people and initiate a social media campaign to make it happen via cooperating different people and encouraging them in line with the aim of the campaign.

On the other hand, sharing economy models may differ with respect to their market mediation, which refers to the mode of exchange. While some require monetary transactions (e.g., Airbnb), others may not require any compensation (e.g., CouchSurfing). The mode of exchange is encouraged by prosocial and altruistic motives or the economic and reciprocal desires of individuals or corporations. However, it is certain that both ways create distinct consumer preferences and experiences in their collaborative consumption journeys. While altruistic urges may necessitate much more emotional feelings about the goods or services, the economic motives put stronger emphasis on the functionality of the products or services.

Summary

The new sharing economy phenomenon has received a great deal of attention among scholars, practitioners, individuals, the media, and the government, since it has changed the traditional definition of transfer of ownership. In this sense,

individuals make their consumption of goods through several activities rather than purchasing. The new form of exchange of goods or services incorporate many different motives inside of consumers such as economic, social, environmental, and hedonic values driving them to engage in sharing-based activities. However, it has changed the mindsets of people and created a huge market potential for both consumers and corporations in the new era of consumption.

[SIGMA Framework](#); [SIGMA Management Model](#)

Definition/Description

The Sustainability: Integrated Guidelines for Management (further on abbreviated as SIGMA) project was launched in 1999, as a partnership between the British Standards Institution (BSI) and Forum for the Future and Account Ability, with the goal of providing companies with the framework on how to become more sustainable (Knight, 2006). The project was strongly supported by the UK Department of Trade and Industry (DTI), and over twenty organizational partners. The developed SIGMA guidelines contain Guiding Principles and a Management Framework, which can be applied in organizations of all sizes and in all industries.

The project's main goal is to improve companies' understanding of sustainability and integrate sustainability concepts in day-to-day operations. To achieve this goal, companies have to develop a set of measures, proper management structures, and a decision-making process (Sitnikov, 2013). Ultimately, the sustainability must become an integral part of the corporate culture.

The SIGMA Management Framework is based on the "Plan, Do, Check, Act" model (Deming, 1982; Sokovic et al., 2010) and has four distinct phases that are rooted in the fundamental organizational processes: Leadership and Vision; Planning; Delivery; Monitor, Review and Report (Knight, 2006; Mertins & Orth, 2012).

The SIGMA guidelines also introduce a SIGMA toolkit, which addresses specific

management challenges, and provides practical templates and case studies for addressing those challenges. Even though the SIGMA management framework was conceptualized as a stand-alone model, it can be neatly integrated with other initiatives like AA1000 Framework and International Organization for Standardization (ISO) 14,001.

SIGMA

The Sustainability: Integrated Guidelines for Management (further on abbreviated as SIGMA) Management Framework is the most substantial part of the SIGMA guidelines. The framework is based on the Plan-Do-Check-Act model (Deming, 1982) in accordance with the following logic: Policy and planning (Plan); Implementation (Do); Verification and assessment of efficacy (Check); Management review and improvements (Act) (Mertins & Orth, 2012). This is not a prescriptive methodology but a rather systematic structure for managing activities and addressing corporate social responsibility (CSR) effectiveness. Further, it is flexible enough to ensure continuous improvement of the sustainability initiatives (through PDCA cycle).

Details of the framework will be reviewed based on the four distinct phases: Leadership and Vision; Planning; Delivery; Monitor, Review and Report (Knight, 2006).

The initial phase is focused on leadership and vision. Strong sponsorship from top management ensures alignment of all processes, systems, and standards, including ones focused on sustainability. During this phase, a vision focused on sustainability is developed, communicated, discussed, and through that process, organizational identity and corporate culture is crafted.

In the planning phase, the overall system is developed based on the company's current state and future desires. After the priorities are set based on the required changes, a detailed implementation plan is developed. As many organizations have CSR and sustainability practices in place, they should use the opportunity to assess them systematically.

The delivery phase is centered around the business model and providing economic logic behind the new actions. Sustainability and CSR programs are implemented in a responsible and accountable fashion while providing value for the end customer.

The monitor, review, and report phase is focused on checking progress and learning and adopting when required. A transparent and timely reporting is particularly important, not only for this phase but all four.

The guidelines provide rich detail for each phase "including suggested activities to focus on: key questions to ask; suggestions for who needs to be involved; potential timing for activities; expected outcomes; further resources, as well as hints and tips to assist with implementation, mapping of what is already underway and establishing what is required" (Knight, 2006, p. 12). The framework provides a structure on how all mentioned elements interact, interdepend, and support each other with the goal of advancing the overall CSR activity.

Many organizations have CSR management, pursue different initiatives through different approaches, and work on continuous improvement. The key distinction of SIGMA is the utilization of the five capitals and accountability as a basis for all CSR and sustainability activity. The five capitals model calls for sustainable wealth creation or "capital" (Ivory & Ascuí, 2019). Organizations use five types of capital: natural, social, human, manufactured and financial for the creation of products or services (Forum for the Future, n.d.; Owen & Kemp, 2012; Porritt, 2012).

The Five Capitals Model

Organizations use five types of capital to create products or services, and attempt to maintain or even enhance the capitals. The model entices organizations to consider how different capitals influence each other and how they impact long-term profitability.

Natural capital, also known as environmental, is the natural resources. All organizations rely on natural capital as they need energy and have an

environmental impact as they create waste. Organizations should consider that some resources are not renewable (i.e. oil, gas), while others are (i.e. timber, water, grain), and with that in mind, try to organize more balanced operations. Further, organizations can enhance natural capital by recycling, re-using, substituting scarce materials with more abundant ones, using renewable energy sources, etc. The importance of such goals is emphasized in the 2030 Agenda for Sustainable Development which was adopted unanimously by the 193 members of the United Nations (UN) in September 2015 (The Grantham Research Institute on Climate Change and the Environment, 2018). The agenda was operationalized through the 17 Sustainable Development Goals (SDG) and 169 targets (United Nations, n.d.-a) widely used by both private and public sectors across the world. The following SDG are focused on environment and natural resources:

- Goal 12: Responsible Consumption and Production. The goal is attempting to ensure sustainable consumption and production patterns. The global “material footprint” like plastic bottles and electronic waste is increasing sharply while recycling data is discouraging.
- Goal 13: Climate Action call for action to combat climate change and its impacts. Most notable issues are the rising global average temperature and greenhouse gas emissions. A positive signal is increase in financing to address these concerns coming from both governments and corporations.
- Goal 14: Life Below Water. The goal is concentrates on conservation and sustainable use of oceans, seas, and marine resources, which is extremely important in the shipping, tourism, fishing industries, just to name a few.
- Goal 15: Life on Land aims to “protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss” (United Nations, n.d.-b, para. 1).

Human capital includes health, skills, knowledge, intellectual contributions, motivation, etc.

Organizations depend on a workforce to function, so they want to ensure individuals are healthy, motivated, skilled, and ready to work. To maintain and enhance human capital, organizations should invest in their workforce, provide training and education, provide fair compensation, create opportunities for advancement, support a high standard of health, and so forth. Several SDG (United Nations a) address these issues, including:

- Goal 3: Good Health and Well-being. The goal is aimed at all ages, and quality of life at any age. The goal is tightly connected to the goal 1: No Poverty, the goal 2: No Hunger, and the goal 6: Clean Water and Sanitation.
- Goal 4: Quality Education aims to “ensure inclusive and equitable quality education and promote lifelong learning opportunities for all” (United Nations, n.d.-c, para. 1). Just in recent years, COVID-19 has wiped out 20 years of education gains.

Social capital is a value-added to economic output through human relationships, such as networks, communication channels, communities, schools, and similar. These social relationships are necessary for organizational effectiveness. Inside the company, individuals build trust through interactions, share cultural values, and ultimately organizations operate effectively. Social interaction is equally important in the external environment, as companies operate in the wider society. Organizations can enhance their social capital by being responsible, paying taxes, obeying laws, minimizing negative social impact, providing safe working conditions through ethical sourcing, and so on. Goals (United Nations a) corresponding to this type of capital are:

- Goal 5: Gender equality. Focus is empowerment of women, their equal representation in decision-making, and equal pay, and all topics that are on the top of many corporate agendas.
- Goal 8: Decent Work and Economics Growth designed to “promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all” (United Nations, n.d.-d, para. 1).

Manufactured capital includes real estate, infrastructure, and technologies owned, leased, or controlled by the organization. Organizations can sustain competitive advantage through manufactured capital while improving efficiency and sustainability. Some of the measures organizations can use to grow their manufactured capital include modular manufacturing systems, zero-waste and zero-emission production systems, reverse logistics with the re-manufacturing system, industrial ecology, etc. Many of which are represented in the following SDG (United Nations a):

- Goal 7: Affordable and Clean Energy. The overall efforts are aimed at higher utilization of modern renewable energy, especially in the sectors like heating and transportation.
- Goal 9: Industry, Innovation and Infrastructure. In the past several years we have witnessed many disrupted supply chains and many closed manufacturing facilities. As a result of that, resilience became a top priority for many corporations and countries. More robust systems are being developed through innovation as well as inclusive and sustainable industrialization.
- Goal 11: Sustainable Cities and Communities is meant to make cities and human settlements inclusive, safe, resilient and sustainable.

Organizational assets in the form of currency that can be owned and traded compose financial capital. They typically include notes, shares, and bonds and reflect the power of other types of capital. Financial capital is the traditional measure of business performance. Sustainable organizations have to understand how economic value is generated. Organizations can enhance financial capital by distributing created wealth, building strong supplier and customer relationships, effectively managing risk, building brand and reputation, and so forth. Some of the SDG (United Nations a) related to the financial capital are:

- Goal 10: Reduced Inequality. The goal is advancing for reduced inequality within and among countries. The COVID-19 crisis

unfortunately, increased the income inequalities in numerous countries around the world.

The final goal, Goal 17: Partnerships for the Goals (United Nations, n.d.-e, para. 2) is focused on facilitation of the sustainable development goals, through global partnerships and joint responsibility of all stakeholders. As mentioned at the beginning, the mentioned 17 goals have 169 interrelated and often interdependent targets, so clearly many goals could be related to the several capitals. The five capitals model remains at the core of conceptual framework, yet the SDG are more operational in many organizations.

Summary

In this entry, the SIGMA Management framework was presented. The importance of the framework was emphasized, given it is at the core of the SIGMA Guidelines and at the core of organizational understanding of sustainability. The framework is a principle-based approach that utilizes the five capitals model and accountability for overall sustainable activity.

Synonyms

Slow Food movement; Slow movement and sustainable food production; Sustainable food movement; Sustainable slow movement in food

Definition

Globalization may contribute to the destruction of traditional lifestyles and culture and hence to some difficulties in the lives of local people. It may also result in barriers to the creation of social movements. However, the Slow Food movement, which can be defined as a return to traditional values in both rural life and urban life, is an opportunity to counter the threat of globalization to traditional lifestyles and is a holistic, space-oriented solution that responds to the problem of sustaining local identity (Sağır 2017). The aim of this entry is to evaluate this trend using the

concept of sustainability and to examine the negative effects of globalization on society and the food industry.

Introduction

People's consumption habits affect their environmental conditions. Particularly, they may pollute their environment by changing the balance of consumption. Environmental deterioration can be viewed from a number of different perspectives, including environmental pollution, deterioration in the number or diversity of living organisms, or deterioration of people's habitats. It also manifests itself in the malnutrition of living organisms (Avgerinou et al. 2019; Türküm 1998). The relationship between the environment and nutritional status has been frequently mentioned in the context of the changing balance of nature and environmental pollution in recent times, especially in the light of the significant increase of the world's population over the last century (Ademowo et al. 2019). The point to note here is that reaching food does not always mean reaching safe food. In order to meet the increasing food demand, which is a result of the increasing world population, some food businesses may need to increase their production capacity. This adaptation may result in negative situations such as compromising the safety of the food produced in some of the enterprises, difficulty in controlling these parameters due to the excess amount of products, or disruptions in the logistics chain (Kasza et al. 2019). Therefore, the food safety concept has gained importance as a way of enabling new generations to reach food while their health is guaranteed (Godfray et al. 2010). The first step in this process was taken in 1972, with the establishment of the United Nations Environment Program (UNEP) (Çevik 2010). The next development was the signing of a charter on biological diversity following the United Nations Conference on Environment and Development in 1992 (Topçu and Topçu 2012). In spite of these important steps, the third Global Environment Report of UNEP in 2002, nevertheless, highlighted little positive change

(Bergman et al. 2015). Despite approximately 2 billion people being healthy enough, more than 1.1 billion people, especially those living in Africa and Asia, could not find potable drinking water; more than 2 billion people were deprived of safe treatment services; and approximately 800 million people had chronic malnutrition problems (Vilakazi et al. 2019). In other words, there were many difficulties in guaranteeing the supply of safe food (Tse et al. 2017). On the other hand, although the numbers were not encouraging, the report did highlight the importance of food safety, and quality food, and healthy eating habits that can be accessed at an affordable price. The most important conclusion was that access to cost-effective food quality should be made possible without disturbing the environmental balance. One of the most effective ways of achieving this is through the application of sustainability principles (Sodiq et al. 2019). By doing so, the environment is not damaged and the benefits can be transferred from generation to generation due to the effective conservation of resources. The Slow Food movement is one way to do this. The symbol of this movement is a small snail (Fig. 1). The snail indicates slowness. In a sense, it also represents the journey of human beings. The slow snail not only can travel surprisingly long distances but also leaves traces where it passes.

The Slow Food movement was created by Carlo Petrini in Italy in 1986 as a response to the growth of fast food. Its main logic is based on the protection of local cuisine, a respect for nature,

and creation of opportunities to eat a healthy and balanced diet. It is an international movement with a total of 100,000 members from 150 different countries (Petrini 2003). In general, slow food is seen as a response to the negative impact of speed on daily life. However, a slow life is not a nostalgic desire to return to the past, to the good old days, or borne out of laziness. On the contrary, a slow life is a process in which daily life is approached with care and attention at its own pace by keeping to routines. Slow life is the art of living in a meaningful, sustainable, thoughtful, and enjoyable way (Andrews 2008). Slow Food also advocates biodiversity in food farming across the globe. It aims to protect domestic or wild animals and vegetable species against the standardization of flavors and supports the consumer's need for awareness. It also seeks to ensure the sustainability of cultural identities to which food and gastronomic traditions depend (Whitehouse 2017). In the literature, the concept of slow food is emphasized in a way that it stands at the crossroads of ecology, gastronomy, taste, and ethics (Hall 2012). At the same time, it opposes the standardization of flavor and culture and is against multinational companies in the food industry and the unlimited power of industrial design (Sağır 2017). For this reason, it takes a place in the food industry with its unique touches such as serving sustainable innovative food products by reflecting the traditional values of societies (Gaitán-Cremaschi et al. 2019). Hence, it is clear that the Slow Food movement can make an important contribution to sustainability. Increasing demand for organic and local foodstuffs and an awareness of sustainability and the importance of quality of life are factors in the Slow Food movement that resonate with the concept of sustainability. As its definition implies, slow food is composed of a good food + clean food + fair food trilogy, and as a result of this, it has adopted the concept of sustainable quality in food (Patrignani and Whitehouse 2018), Tolstokorova 2018, www.slowfood.com). The sustainability of food quality should not be left only to food production and the food supply system. At the same time, each individual should be responsible for preserving local food, traditions, and cultures

Slow Food Movement and Sustainability, Fig. 1 The symbol of the Slow Food movement (source: <https://landinstitute.org>)

(Petrini 2003). These features should be regarded as valuable treasures that should be well-preserved and documented from one generation to the other (Cabeça 2018). Today, ensuring the continuity of traditions and social values has become one of the important values of not only individuals, families, and farmers who earn their living from food, but also companies (Bashutkina 2019). An example would be working life in Japan. Discipline, group spirit, loyalty to authority, religion, and national spirit are some of the main factors that have influenced the development of Japanese industry (Liao et al. 2016). Loyalty to the group was directed to the business group, loyalty to authority was directed to the boss or supervisor, loyalty to the state turned toward the company, and individuals became identified with the job. The success of the business and the success of the company have been a requirement of the individual's national feeling toward the state (Murat 2012). Moving from the same scope, it is possible to encounter reflections from traditions in activities held in other businesses. For example, in Muslim societies, some companies offer special meals for the month of Ramadan. They serve traditional food and use entertainment tools such as public theatre performances, shadow puppet theatre shows that have become cultural symbols in the entertainments during the Ramadan period (Kızılbulut 2019; Odabas and Attar 2018). Therefore, the sustainability of traditional values can be realized in different areas as in the examples mentioned.

Developments in this approach in the field of food allow the Slow Food movement to spread (Altuna et al. 2017). The Slow Food movement is spreading rapidly, supporting the idea that people are striving for sustainable, healthy eating. This entry examines the Slow Food movement in the context of the concept of sustainability.

The Emergence of the Slow Food Movement

Carlo Petrini, an Italian gourmet, started the Slow Food movement in response to the opening of a McDonald's restaurant in Piazza di Spagna in Rome in 1986 (Petrini 2003). A group of political and cultural Italian activists prepared a manifesto for the movement. Its focus is on the negative

effects of people having to live life at a fast pace. Therefore, this movement should not be seen only as a reaction to the opening of a McDonalds. The Slow Food movement aims to raise awareness about the role of fast and mass-consumed foods in peoples' life balance and to find ways to combat the rapidly growing fast food sector by finding alternative food solutions. Food businesses that produce good quality small-scale food with sustainable techniques are also included in this movement. It is accepted in the manifesto that globalization provides advantages in some areas but that it also harms the environment and can produce negative effects on life and eating patterns. Examples include the negative impact it has on the agricultural sector; the standardization of taste in some mass-produced foods; the deterioration of the seeds of fruits and vegetables produced from domestic sources; the selection of crops; and health problems caused by ready to eat foods. In short, the Slow Food movement was established to emphasize that there are individuals or living organisms that cannot keep up with all the developments brought about by globalization, and that this creates problems in the system (Hendriks et al. 2017). For this reason, almost all of the activities are dominated by adaptation to individuality, support for a sustainable approach, and the motto that food culture is an integral part and representative of society. Table 1 gives a chronological list of activities organized within the scope of the Slow Food movement. The expected outcomes of these activities include raising awareness of gastronomic pleasures to a society accustomed to fast-food culture; emphasizing the importance of enjoying freshly cooked food; educating consumers to respect nature and agricultural diversity; and preserving regional food cultures (Petrini and Padovani 2006). The movement is democratic in nature and based on the principle of volunteerism. The volunteerism principle is strategically placed in the formation of the Slow Food movement (Clancy 2017). Volunteers function as motivators in activities and the achievement of success. Volunteers support many issues, from guiding participants to activities, working as facilitators in workshops, managing events in the field of sustainability, and

Slow Food Movement and Sustainability, Table 1 Advantages and disadvantages of the Slow Food movement

Advantages and disadvantages of the slow food movement
<i>Advantages</i>
It encourages the production of local products. Therefore, a contribution is made to the national economy (Snyder et al. 2018)
It is profitable for local producers and provides earnings for local sellers (Counihan 2016)
It contributes to the spread of naturally produced food products. The naturally produced food products lead to significant short- and long-term health benefits for consumers by having better taste, supporting immune system, and providing improvement in general health condition with their rich nutrient content such as antioxidants, vitamins, and minerals (Goldberg 2012)
It supports sustainable agriculture by conducting studies for the continuation of biodiversity (Munjal et al. 2016)
It encourages researchers to carry out projects to prevent the food products that are threatened with extinction (Fontefrancesco and Corvo 2019)
<i>Disadvantages</i>
Some naturally produced food products are expensive, and not everyone has the budget to buy them (Haws et al. 2017)
In order to produce more products, more agricultural land is needed (Snyder et al. 2018)
Food distribution is more complicated (nonorganic food and organic food cannot be transported together, which leads to increased transportation and storage costs; there are risks of product contamination between organic and nonorganic food) (Hansmann et al. 2020)
If developed countries focus on local food production, the demand for imported food products may decrease as a result of encouraging local food production. This situation creates a disadvantage for less developed countries where a part of their livelihood is the export of agricultural products (Barragán-Ocaña et al. 2019)

ensuring efficient interaction among participants (Markwell et al. 2012). They also take roles in formation of local groups called “convivia” (Pietrykowski 2004). The convivia is the plural form of the name “convivium” (Jacobs 2013). The conviva are known as types of local communities and are run with the help of volunteers (Hatipoglu 2015). The members of the convivia work to integrate the basic principles of the Slow Food movement as much as possible into their daily life. As the movement expands, its activities are spreading all over the world. The activities are about many different themes such as ensuring food safety by preserving food biodiversity, preserving food quality, bringing producers and consumers together on appropriate platforms, and raising awareness of the society on conscious food consumption (Voinea et al. 2016). As can be seen from this diversity of activities, activities within the scope of Slow Food range from local to international projects (Fontefrancesco and Corvo 2019). The development of innovative travel methods, such as Slow Food Travel destinations in order to ensure the recognition of the foods

specific to the culture of the countries, and the preservation of food and food culture varieties that are about to be forgotten with biodiversity studies are some examples of these multi-disciplinary initiatives (Nässén 2017).

Slow Food Movement Principles

Slow food starts with good, clean, fairly produced food. In particular, the movement seeks to combat standardization in order to preserve local tastes and different cultures within a country. In addition, other principles have been adopted to promote access to quality food by providing sustainable conditions (Pietrykowski 2004):

- To protect nature, local biodiversity, and cultural heritage and to establish a seed bank for this purpose
- To adapt to the natural rhythm of life
- To protect and to promote local and traditional nutrients
- To promote organic farming and to protect products from genetic engineering interventions

- To save animal lineages, cereals, and fruit and vegetable seeds from extinction
- To support local producers
- To know what people eat and how that food is produced
- To improve the productivity of local farmers
- To conduct scientific studies to prevent the loss of local products
- To facilitate taste (flavor) training
- To raise awareness about producers and production methods
- To turn peoples' tables into feasts

When these principles are evaluated, it is clear the Slow Food movement is not about getting enough food. What is more important is the taste of that food and establishing a social setting in which to enjoy it with others. Moreover, the concept of slow food encompasses a wide spectrum of food and nutrition issues, including the environment, agriculture, politics, finance, and culture (Sidali et al. 2011). People's preferences for certain foodstuffs obviously affect the market for those products, and the economic development of the region where they are produced, as well as the distribution channels. Moreover, this demand impacts export-import balances, and even the culture of people working to produce the foodstuffs (Cheremisina et al. 2019). In this sense, various constructive activities are organized by members of various *convivia* to influence production in line with the movement's principles. These activities include the promotion of new kinds of food products and analysis of feedback on them. Thematic workshops also showcase local culture and food expertise for consumers (Stančová and Cavicchi 2019).

Advantages and Disadvantages of the Slow Food Movement

Every activity and every principle in any field has its advantages and disadvantages (Hall 2012; Nosi and Zanni 2004; Kjørstad 2017). The advantages and disadvantages of the Slow Food movement are summarized in Table 1.

As can be seen from Table 1, the Slow Food movement approach may provide advantages in some issues but may lead to disadvantages in

some areas. It is possible to examine the factors mentioned in the table under the headings of economy, health, and environment in general. It is clear that the food products and opportunities offered by the Slow Food movement serve the society with a healthy nutrition philosophy (Voinea et al. 2016), because the food products are produced using traditional methods, on the local land, and utilizing local labor (Thomé-Ortiz 2018). It is clear that this brings benefits in terms of nutritional value of the food product. Hence, the movement is also open to new research and collaborations in food industry (Altuna et al. 2017). Being related to food industry, when considered from an environmental perspective, it is seen that it does not harm nature due to the adoption of its environmentally friendly policy (Chung et al. 2018). In doing so, contribution is made to the national economy in areas such as local food production, encouragement to local food consumption, increase in trade, and contribution to the tourism sector (Snyder et al. 2018; Counihan 2016).

However, the approach may sometimes not be cost-effective in production and purchasing, because production costs are high and larger area of agricultural land is needed to increase production (Ren et al. 2019). In addition, the logistics chain must be well planned. The logistic chain is practical, because this movement reduces the distance between the producer and the consumer (Rodrigues et al. 2020). Even if food products are purchased directly from the producer or bought from the market, individuals must be conscious and careful about food product safety. Otherwise, it is possible to observe negative consequences such as rapid deterioration, degradation, and contamination from other products (Hansmann et al. 2020; Ahmed et al. 2019).

Sustainable Development and Food

Since it contains many variables, studies on the concept of sustainable development indicate that there is no consensus regarding a precise definition (Sinakou et al. 2018; Noe et al. 2017). However, it could be said to be the ability of any system or ecosystem to sustain activity and production in the long term with a general approach

without disrupting, overusing, and overburdening resources (Van Marrewijk 2003; Glavič and Lukman 2007). It has three interrelated dimensions such as social, environmental, and economic (Domańska et al. 2018; Lele 1991) (Fig. 2).

Economic sustainability is the ability to produce goods and satisfy needs in the future. It avoids approaches that adversely affect agriculture and industrial production and protects welfare, resources, and the capital. Welfare is a central concept in the economic interpretation of sustainable development (Mikulčič et al. 2016). The probability of resource depletion has an important place in the economic dimension of sustainability (Székely and vom Brocke 2017). Because of this probability, sustainability has always been a central element of the renewable natural resources' economy. This criterion should also be considered in predicting business risk factors (Ighravwe and Babatunde 2018).

The environmental dimension of sustainability does not approach the environment solely with economic concerns. Environmental sustainability covers the continuation of the existence of resources in the future, a preference for renewable resources, and the limited use of nonrenewable resources (Güney 2019). Concepts that have no economic value, such as biodiversity, atmospheric equilibrium, and the maintenance of other

ecosystem functions, are also considered within this element (Sandberg et al. 2019). In this context, while environmental science investigates the sustainability laws of subhabitats, it focuses more closely on the broad framework outside of all systems through the environmental economy. For example, there is no substitute for clean air. In addition, water resources are not only an economic resource or even just one of living conditions. It is an environmental element that is related to many subsystems and other living systems. In this context, environmental sustainability can be defined as preserving valued things or qualities in the physical environment (Springmann et al. 2018). These concepts are also among topics of particular focus for sustainable food production and the Slow Food movement (Fontefrancesco and Corvo 2019).

Although sustainability studies are always handled on the axis of economic and technological approaches, the aspect of the issue related to society and individuals reveals the importance of social sustainability (Domańska et al. 2018). The social dimension of sustainable development emphasizes meeting the basic needs of the society (Domańska et al. 2018). A socially sustainable society must have the flexibility to protect and develop its resources and to prevent and/or solve problems in the future. In addition, social

Slow Food Movement and Sustainability, Fig. 2 Three dimensions of sustainable development (Domańska et al. 2018)

sustainability is an indicator of the level of social quality (Ballet et al. 2020). Hence, it is possible to evaluate a society depending on the approach to the issues such as human rights, gender equality, and access to health, social services, and human relations within the scope of social sustainability. These issues are also important within the Slow Food movement (Agarwal 2018). Therefore, it is possible to say that the Slow Food movement can act in accordance with the principles of sustainable development (Fontefrancesco and Corvo 2019).

When the three main elements of sustainable development are examined, it becomes a natural necessity to associate the concept of sustainable development with food (Asian et al. 2019; Viljoen & Wiskerke 2012; Brklacich et al. 1991). The concept of sustainable development is to protect the cultural integrity, ecological processes, biodiversity, and life-sustaining systems by preserving the environment in which human beings interact, without disturbing or changing that environment (Waas et al. 2010). In fact, the starting point and aim of the sustainable development concept coincides with the principles of the Slow Food movement trend and provides integrity within it (Morgan and Sonnino 2013), because these concepts feed on the same basis that agriculture is one of the initiators of the sustainable food chain (El Bilali 2018). When it is associated with sustainability, systems and practices will continuously improve the production of adequate and high-quality agricultural products at an affordable cost which are included for the protection of agricultural land, farmers, environment, and natural agricultural resources. Therefore, “Good Agricultural Practices” regulations have been developed and implemented in almost every country in recent years (Leong et al. 2020; El Bilali 2018; Swanson 2008). Another approach that has been adopted to ensure sustainability in the field of food and agriculture is “Green Economy Practices.” The green economy approach, which has been handled in international platforms in recent years, is a recently focused and developing concept. For this reason, although it contains partial differences in the literature, it usually has overlapping definitions. In this context, definitions of green

Slow Food Movement and Sustainability, Table 2 Definitions of green economy (Aoki-Suzuki and Managi 2015)

Source	Definition
United Nations environment Programme (UNEP)	Ensuring human welfare and social equality in low-carbon, environmentally sensitive jobs
Organisation for economic co-operation and development (OECD)	Ensuring the continuity of the environment and development, the creation of new investments and employment
World Bank (WB)	The efficient use of natural resources by minimizing environmental damage
United Nations (BM)	Employment-based growth while preserving the environment and creating new job opportunities and ensuring the sustainability of economic growth
United Nations economic and social Commission for Asia and the Pacific (UNESCAP)	Providing sustainable economic development that is environmentally sensitive by promoting low carbon

economy in international platforms are given in Table 2 (Destebaşı et al. 2015).

When the overlapping points of the definitions of various international organizations for green growth are evaluated together, the green economy can be described as a tool that ensures the sustainability of the environment, increases social welfare, supports clean technologies and innovation, strengthens economic growth, and increases new job opportunities in order to achieve sustainable development by using natural resources efficiently and preventing environmental degradation. The green economy approach requires technological and structural changes in many areas such as production and consumption patterns, planning, infrastructure, employment, and workforce structure (Aldieri and Vinci 2018). It is possible to evaluate these changes in the green economy process as an advantage and unifying factor. Following the green economy path requires investment in new technologies, new products,

new equipment, and new infrastructures (Lorek and Spangenberg 2014).

Sustainable food production is one of the areas for investment in a green economy (Newton and Cantarello 2014). The industrial activities of the green economy do not only include energy production and food activities without damaging the environment, but also the activities that bring industrial production in harmony with nature. In this context, the green economy includes treatment plans for waste disposal, constructive approaches for the efficient use of resources in food production, activities for the restoration of degraded natural areas, renewable energy systems, minimization of carbon footprint, and many other research and development activities (Loiseau et al. 2016). Sustainable food systems associated with the green economy are also defined as the processes in which individuals or groups cooperate with each other in relation to food, and form their own structures (Brears 2018). These structures and processes include production, processing, distribution, wholesale and retail sales, consumption, and waste disposal, which are also some of the important issues for the Slow Food movement.

The Slow Food Movement and Sustainability

The food industry is in a period of rapid change on account of a number of different factors such as market economy status, food production conditions, consumer profile, consumer perception, raw material supply, etc. (Santeramo et al. 2018). Some of these developments are desirable, but some may have negative results. For example, consumers' choices are effective in food purchasing decisions. The characteristics that affect the purchasing behavior of consumers are demographic (individual characteristics such as age, gender, marital status, income, education, and occupation), socio-cultural (family, counseling groups, social class, and culture), and psychological (motivation, perception, learning, beliefs, and personality) (Jensen et al. 2019). In this case, it is necessary to produce food by considering the characteristics of the target consumer segment. In addition, consumer perception is another

concept that can be investigated within this scope. For example, the occurrence of some diseases at certain times or seasonally may cause inappropriate concerns in the society that malnutrition triggers cancer due to rumors, even if the target food has not a negative side case (Eryilmaz et al. 2018). In particular, a number of companies are breaking or bending regulations to get ahead of the competition. However, although the sector is currently large, it is likely to shrink dramatically if resources are not used effectively or if the food production process is not managed efficiently (Öndeş et al. 2011). One of the reasons for the emergence of sustainable development is the need to find solutions to these potential problems.

In addition, the Slow Food movement is not only concerned with food production, but also has various principles regarding food culture (Fusté-Forné 2019). It aims to encourage the production of food using local materials, to preserve traditional recipes and to deliver those food products to visitors in a traditional way. In this way, the Slow Food movement aims to preserve cultural values as well as sustainable food production. Other common points of sustainable food production and the Slow Food movement approaches are summarized as follows (Heitmann et al. 2011):

- To improve access of all community members to adequate, nutritious, and healthy food
- To support small family farming and ensure sustainable agriculture practices
- To ensure direct connection of consumers and producers in processing and marketing processes
- To ensure the recirculation of financial capital and creation of job opportunities in food- and agriculture-related enterprises
- To improve the working and living conditions of the labor force in the farm and food system
- To support local production, processing, and consumption

Research shows that local products are being sold in sustainable food systems and that products are being produced with sustainable agricultural systems, thus preserving natural resources,

especially local seeds (La Trobe and Acott 2000). At this stage, producers play an active role in improving producer and consumer interaction and increasing community solidarity (Opitz et al. 2019). In these systems, where intermediaries are not present, it is also stated that the producers receive the value of their labor, while consumers do not have to pay excessive prices for environmentally friendly foods. Moreover, money that is spent by consumers stays in the local economy and strengthens the position of small producers. This mechanism increases the fresh and nutritious food product variety in farms, and therefore, it contributes positively to human health (Apak and Gürbüz 2018). In sustainable food systems, food safety and security, health protection and development, prevention of diseases, protection of nature, protection of agricultural biodiversity, strengthening of local and rural areas, and socio-economic development are all facilitated together (Béné et al. 2019a).

Summary

To counter the negative effects of industrialization and globalization on agriculture and food production, the Slow Food movement is becoming increasingly important in the world within the framework of ecological and social sustainability principles. It may not be possible for everyone to reach clean, organic food without genetically modified organisms today. However, the Slow Food movement aims to improve this situation in the future (Fontefrancesco and Corvo 2019). In addition, it raises awareness of these issues and constitutes a driving force in society. There have been various discussions about the importance of food, eating habits, and environmental conditions to human health (Zonneveld et al. 2019; Voinea et al. 2016). All of these things follow the basic philosophy of the Slow Food movement. Moreover, the Slow Food movement has a strong connection to sustainable food production. These concepts have economic, health, and environmental advantages, but both approaches can be costly (Altuna et al. 2017; Sağır 2017). For example,

more agricultural land is needed for the production of a wide variety of abundant and safe food. This requirement can affect the economies of less developed countries (Snyder et al. 2018). Still, it is clear that Slow Food movement initiatives are important and can help make food production more sustainable (Dixit 2019).

The use of sustainable food systems to retain food safety and food quality has been demonstrated in many studies to be achievable (El Bilali 2018). The global sustainability map can be considered as an example in this context. The map considers not only production and nutrition, but also economic and social variables. In this context, about 20 years of scientific literature on food systems was scanned, and 20 variables that can be obtained for 97 countries data were determined. The variables can be used to monitor the effects of sustainability changes in phenomena that put pressure on the global food system such as changing climate, increasing population, and increasing food demand (Béné et al. 2019b). As can be seen from the example given, in order to create a fairer and more sustainable world, the use of the Slow Food movement approach will help consumers become more socially aware and responsible. Its impact on both food and sustainability contributes to the development of food production (Nässén 2017).

Definition

The percentage of the world population living in cities is increasing. While around 55% of the world's population inhabits cities now, it is expected to reach 30% by 2030. The inhabitants provide and require uninterrupted access to many diverse services and infrastructure such as transportation, health, energy, education, and security. The traditional city infrastructures are not designed to deal with an increasing load and have inadequate resources. Therefore, the concept of the search for an ideal city has emerged in order to overcome the urban problems experienced after the industrial revolution. Since the 1980s, the widespread use of information and communication technologies has led to concepts such as information cities, smart cities, digital cities, virtual cities, and wired cities. The concept of a smart city is a participatory and sustainable urban development vision that aims to establish effective city management to meet public needs in accordance with the needs of the era and to increase the quality of life by using information and communication technologies. For a city to be defined as a smart city, it is necessary to evaluate the city's every component, not just smart electronic devices and software. Smart cities can be analyzed under the components of smart governance, smart economy, smart person, smart life, smart mobility, and smart environment, as shown in Fig. 1.

Introduction

Throughout history, members of the profession such as urban planners, architects, environmentalists, social scientists, administrators, and citizens have put forward various ideas for creating better urban spaces. While the creation of concentrated urban areas by these groups sometimes came to the fore, sometimes the protection of traditional areas with lower density was emphasized. In the same way, while sometimes public transportation-oriented development is at the forefront, sometimes environmental-oriented urban development has gained value. However, according to a report published by the United Nations in 2016, cities are

Smart Cities,

Fig. 1 Components of smart cities

the settlements where approximately 54.5% of the world's population live, make a living, and receive services. Also, the population continues to increase exponentially each year and by 2030, this number will rise to over 60% (United Nations 2016).

After the industrial revolution, the inadequacy of traditional city infrastructure became evident. In the decades before 2000, negative pressures on nature such as global warming, greenhouse gas emissions, and environmental pollution became a global problem, which caused approaches such as green city, eco-city, slow city, and habitable city to appear. Since the 1980s, the widespread use of information and communication technologies generated concepts such as information cities, smart cities, digital cities, virtual cities, and wired cities. Moreover, in today's cities, providing uninterrupted access to services and infrastructure, such as transportation, health, energy, education, and security became of great importance. Therefore, the concept of smart cities, aiming to create a better urban area and increase the quality of life by making use of technology, has directly affected modern societies and urban

life. Especially after the 2000s, the rapidly changing and developing technology has affected every aspect of life. Developments and rapid transformation in information and communication technologies have generated various urban planning and expansion approaches.

The concept of a smart city is a participatory and sustainable urban development vision that aims to establish effective city management in order to meet public needs following the needs of the era and to increase the quality of life by using information and communication technologies. One of the alternate smart city definitions in literature is as follows: "These are cities where critical infrastructure components and public services such as urban management, education, health, public security, real estate, and transportation are made smarter and more efficient, interconnected, using intelligent information technologies." (Washburn et al. 2010). Conceptual relatives of the smart city include digital city, intelligent city, virtual city, ubiquitous city, and information city (Ishida 2017). Although these definitions are conceptually relative, they differ from each other at certain points, yet they overlap

with each other in terms of starting point and content.

To define a city as being a smart city, it is necessary to evaluate every component of the city, and not just its smart electronic devices and software. Smart cities can be analyzed into six components. These are smart governance, smart economy, smart person, smart transportation, smart life, and smart environment (Aldairi and Tawalbeh 2017; Deloitte and Vodafone 2016). Figure 1 shows the main components of a smart city.

The Main Elements of Smart Cities

Another way of looking at smart cities is through their utilization in providing services. These services consist of the tangible and intangible elements of a smart city. The elements can be integrated, managed from a center, or be discrete self-governing entities. They include GIS integration, management from a single center, and the management information system, disaster and emergency systems, transportation, buildings, environment and infrastructure, data collection, and health.

GIS integration: The methods that enable the collection and analysis of various geographical data to solve the problems faced by cities in the fields of ecology, socio-economy, and planning are called GIS. GIS supports to make rational decisions by making location-based analysis.

Management from a Single Center and The Management Information System: It is a database programmed to produce regular reports on the work and transactions carried out for each management level in an organization. While performance measurement is realized employing the digitalization of workflow processes; it aims to monitor management processes in an effective, high quality, and reliable manner and to report to decision-makers about the process.

Disaster and Emergency Systems: Intelligent natural disaster and emergency systems are created to prevent natural disasters, take precautions against natural disasters and minimize the damages that may occur as a result of natural disasters.

Notifications can be made before, during, and after the disaster by providing interaction between public institutions and citizens through smart applications (Yaman and Çakır 2018). Applications such as disaster information systems and smart maps are used in smart natural disaster and emergency systems.

Transportation: Transport management in smart cities is performed by an electronic traffic and transportation control system. It aims to make urban traffic more functional and safer by making traffic measurements, observation, and information. It is the general name of the systems that enable actions such as in-vehicle and road tracking, location tracking, station and route information accessed live by the users, and the management point through various applications. These systems increase the quality of service and life in cities. Although many cities today are not smart, they make use of a smart transportation management system. Intelligent transportation system, license tag recognition, speed measurement, acceleration of traffic flow, preparation of statistical reports, detection and recording of rule violations form smart hardware and software. As part of smart public transport, the system in which information such as speed, route, location, and arrival time for all vehicles used in public transportation is presented to passengers in real-time is called a smart station system. It has an aspect that increases citizen satisfaction by shortening the waiting time at the station and facilitating public transportation for disadvantaged individuals such as the disabled, especially thanks to audio information applications.

Buildings: Buildings are a whole with their architectural design, carrier system, building material, siding, installation, and automation systems. The concept refers to the digitization of all equipment such as heating, cooling, ventilation, elevators, fire and security alarms, recycling systems, lighting to increase energy and resource efficiency and improve the quality of life. New types of smart buildings as well as a remote-control system with artificial intelligence technology enable building management according to data sets. For example, an artificial intelligence elevator system is expected to manage elevator traffic

more efficiently and appropriately through the data it collects during its service.

Environment and Infrastructure: Measurement and control activities for resources are carried out with the help of information and communication technologies for environmental sustainability. The use of technology in line with the goals of rationalizing meters and establishing monitoring systems, rationalizing buildings and structures, smart management of waste and water, promoting renewable energy, and reducing carbon dioxide emissions take place under this heading.

Central Supervision Control and Data Acquisition (SCADA): This term is an abbreviation consisting of the initials of the words Supervisory Control and Data Acquisition, and refers to a system that monitors, controls, collects data, and stores data to benefit in terms of cost, speed, security, and quality. Instant monitoring, remote control, and intervention operations can be implemented through this system, which is especially used in energy facilities (nuclear, natural gas, electricity, etc.), production facilities, and control centers (traffic, earthquakes, etc.).

Smart Grid and Smart Meter: By integrating the grid systems with computer and network technologies, monitoring and control activities can be realized in network systems. In this way, a sustainable, optimized, and secure network system can be created by providing real-time and two-way information flow at all stages, from production to consumption. Energy and communication lines and transportation systems are an important part of smart cities when they are built with smart grids. Smart meter, which is an integrated part of smart grids, refers to a digitalized hardware. As it makes precise and frequent measurements, it provides real-time transmission of information about the power reaching the meter and the amount of consumption. This provides detection and efficiency in a wide range from loss-leak detection to investment planning.

Health Services: Smart health systems use mobile communication and network technologies for many health services such as improving healthcare services, reducing healthcare costs, increasing the quality of life of patients, early

diagnosis of diseases, and quicker intervention for people in need of healthcare. The use of smart healthcare systems significantly helps to reduce healthcare costs. Thanks to early detection and prevention mechanisms, patients receive less treatment, there are fewer unnecessary recurrences, and deployed systems are used more efficiently (Solanas et al. 2014). Intelligent health systems are used with applications such as e-pulse, e-prescription, and central doctor appointment system.

Technology in Smart Cities

Nowadays, the integration of technology with cities is inevitable in terms of both livability and sustainability. One of the most important elements that distinguish smart cities is undoubtedly the application of technologies that take human life at its center and aim to better the quality of life. The use of technology helps to determine the needs of citizens and meet their needs more efficiently. Thus, private and public institutions will be able to provide better services. State of the art smart city technologies can be listed as follows: mobile devices, digital platforms, the internet of things, big data, open data, 3D printing, socially interactive robots, driverless vehicles, drones.

Mobile devices and digital platforms: Mobile or portable devices rapidly entered human life with the beginning of the information age and immensely impacted and changed ways of living. Historically, accessing data has never been easier than today. These devices provide a wireless internet connection and GPS signal to the user anytime and anywhere. One of the most important factors that make mobile devices impactful is the increasing number of mobile applications every second. Mobile applications provide the focal point, where the service provider reaches the user, brings together many services including transportation, entertainment, health, banking, and security. Digital platforms that provide services through mobile applications create new business models for private institutions and public institutions and play an effective role in human life in social,

economic, and cultural terms. GPS signals, location information, and many different and private data they store are analyzed by service providers and returned to the user as customized service. Mobile devices are also one of the channels through which city services are delivered to the user for smart cities, which are based on the interconnection of each actor. Connecting to the city's wireless network access points with these devices make the users a living part of the city's technological infrastructure. Thus, mobile devices serve as a channel through which smart solutions offered by the smart city can be accessed. If the applications installed on mobile devices and access to the digital platforms are examined, it is seen that the services provided by the public sector and municipalities take place more efficiently and intelligently due to mobile applications.

Open and Big Data: Big data, which has been frequently heard in recent years, has been defined by Microsoft as follows: "Big data, is the process of applying serious processing power, machine learning, and artificial intelligence algorithms to seriously large and often very complex information sets." (Microsoft 2013). The amount of data collected all over the world has reached significant levels with the introduction of computers into human life. The advancing technology and developed algorithms can make more meaningful inferences, which have reached enormous dimensions.

With the increasing urban population, the quality of service provided by the physical infrastructure of the cities is insufficient. The necessity of providing smart solutions has emerged to collect infrastructure inputs in a city and to process this large amount of data. Big data provides useful insights for smart cities from data collected from devices such as RFID tags, sensors, and tracking devices, and distinguishes smart cities from traditional cities. Thus, it is easier to detect inefficient use and waste of resources, which can be prevented by constant monitoring and recording the tally of resources. Moreover, with the resources that will be distributed more efficiently, the energy to be spent and the damage to nature can be minimized (Al Nuaimi et al. 2015).

Presenting the collected and analyzed data clearly will increase the transparency of smart city management, facilitate decision making, and more different and efficient service areas will emerge by encouraging sharing. This idea appears as an open data concept. Open data is basically defined as freely used, reused, and distributed by anyone (Open Knowledge Foundation 2012). With the evaluation of open data, the participation in cities will increase and it will be easier for multidisciplinary work. At the same time, transparency in management will be ensured by making data such as election data accessible to people by administrations.

Internet of Things (IoT): The internet of things can be defined as the creation of new usable services that will enable all kinds of electronic devices to communicate with each other and with other services over the internet by gaining sensing, feeling, networking, and data processing capabilities. With the development of technologies such as internet technologies, sensor networks, and RFID, the communication and processing capability of technological objects with each other has increased. The internet of things concept forms the basis of smart services offered in cities. One of the most important elements in the digital infrastructure of the city is devices that communicate with each other. The many services in smart cities collect necessary data using the internet of things. In smart cities that aim to utilize energy resources in the most efficient way, smart grids are integrated by using the internet of things. More efficient energy services can be provided to users with the data collected by objects that communicate with each other and have sensory features. As the type of data to be collected and the quality of the analysis increase, so does the variety of services that can be provided.

3D printing: 3D printing, in other words, additive manufacturing, is the conversion of digital data into 3D objects. Nowadays, 3D printing technology started to be embedded in smart city strategies, where the importance of increasing productivity is frequently emphasized. To meet the housing needs of people, the use of this

technology is thought to be easier, more efficient, and faster. WinSun company built the world's first 3D printed home in China and claims that it can build ten houses within 24 h (Starr 2015). It can also efficiently use recycled materials from 3D printing devices. The reuse of old or unusable houses, furniture, and all kinds of urban objects with 3D printing will increase the quality of life and contribute to the upcycling of unused materials. In the following years, a whole city can be produced with 3D printing with the developing technology.

Socially interactive robots: With the integration of technologies such as artificial intelligence and machine learning with robot technology, the concept of socially interactive robots emerged. The most important point distinguishing these robots from traditional industrial robots is that they can adapt to change and have features related to learning. Robots, which do the work of people in many fields such as education, health, housework, with less cost and less error, will become constant parts of smart cities (Flandorfer 2012). Robots will take part in many areas such as warning the officers in emergencies, cleaning the city, reporting the deterioration of the roads, as well as rescuing people from burning buildings, cleaning and maintenance of large buildings, and being of use in the service sector (Torras 2016). However, while some argue that decreasing the job opportunities for people is a drawback of increasing the contributions of robots to cities, others argue that they will leave people to do more of the work they desire. Another ethical problem is the rights and responsibilities of robots as intelligent beings.

Drones: There are many areas in smart cities where drones can be used to make city life more sustainable. The primary areas are geographical measurements and data production by equipping the necessary equipment for measurement, informing the authorities by detecting violations of security by monitoring the city from above or from inside, providing data about traffic conditions and detecting traffic rule violations, operating in the fields for fertilization, irrigation, natural disaster in search and rescue operations, and transportation of various products in agriculture. When the necessary infrastructure is provided for the use

of drones, they will play an important role in smart cities (Mohammed et al. 2014).

Best Practices of Smart Cities

In the smart city definition of IHS, a London-based information provider, the number of smart cities is expected to increase from 21 in 2013 to 88 by 2025 (IHS Markit 2014). In this context, three smart city best practices are discussed as examples.

Copenhagen: Copenhagen has a population of approximately 1.2 million. According to the smart city index made by Sweden-based EasyParkGroup company, the city of Copenhagen was evaluated as the smartest city with an average score of 8.24/10 under the seven categories (EasyPark 2017). Copenhagen was also selected as the green capital of Europe in 2014 since it is taking firm steps toward its goal of becoming the first city to reduce its carbon dioxide emissions to zero by 2025. In the bulletin published on the way to becoming a smart city, the main goal was to increase the quality of life, growth, and sustainability (The Ministry of Housing, Urban and Rural Affairs 2015). The city clearly presents its smart city strategy and shows how assertive it is in this regard with its large-scale investments as well as planning. In order to achieve its goals, a project coordination board has been established with the cooperation of seven public units. The coordination board moves smart city projects with a single strategy. In this respect, projects are planned and implemented with four basic principles. These are the use of the collected data in problem solving, the use of new technologies or known technologies with new methods, the efficient use of the municipal or city budget, and the use of new methods to involve people and businesses in the process. The principle of participation and interaction of all the elements of the city is one of the most important prerequisites of being a smart city. The Copenhagen project coordination board provides this in production and implementation of projects with the aim of city residents contributing to city development by sharing data and feedback. New road maps are drawn with the feedback of

both Copenhagen's seven public units and city residents, and existing systems are also improved based on feedback. Thus, city residents can report defective city elements that do not work with the mobile application, as well as share their improvement and new project ideas on this platform (The Ministry of Housing, Urban and Rural Affairs 2015).

Singapore: The city of Singapore is the capital of the Republic of Singapore with a population of 5.5 million. The city has a population of 3.5 million, who live in urban areas. Singapore is an example of Asian economic development and is the most important model for city-states in terms of change and innovation. This city is a global financial center despite its lack of natural resources. It is important in terms of providing an open business environment to the society, making technology-oriented investments, and having a revolutionary education system (World Cities Culture Forum 2018). Due to its geographical location, its efficiency in airline and maritime transportation, and its tax policy, Singapore is like a threshold at the entrance of the Asian market for large technology companies. The country hosts the centers of technology giants such as Razer, Red Hat, and IBM, and its capital city of the same name is a regional center for technology. The smart mobility approach in Singapore is dominated by rail. In Singapore, 80% of citizens live within 10 min of walking distance to a train station, and 75% of the people prefer using public transportation during peak hours. Moreover, reducing vehicle dependency and developing an environmentally friendly solution led to the planning of a 700 km bicycle path network to be finished by 2030 (Benner 2016). Today, data sets are considered a new type of currency and are made available to the public online. Data sets from 70 public institutions were made available to everyone through a portal to support solutions for the benefit of society and to ensure transparency. This data portal is a data repository that contains data on the economy, education, environment, health, infrastructure, society, and transportation. Static and real-time data on land transportation are shared with the public through the application named LTA DataMall to create

innovative and comprehensive solutions together. Singapore monetary authority, a financial regulatory agency, shares its data sets and software application interfaces with financial institutions and service providers through the application called MAS API. Citizens control the sharing of their data in online jobs through the application named MyInfo, also designed by the Singapore government.

Stockholm: Stockholm is a city that hosts various educational, scientific, and cultural institutions, and the center of many national and international companies such as Ericsson, Skanska, Klarna Group, in particular banks and insurance companies. Stockholm also serves many offices of the national government. Stockholm Municipality aims to make public services easier, more developed, more comprehensive, and more efficient thanks to the electronic services offered, and offers e-services in more than 70 areas. Within the scope of the Horizon 2020 program, the GrowSmarter project was carried out with 40 stakeholders under the coordination of Stockholm Municipality between 2015 and 2019. Twelve smart city solutions such as smart traffic management, big data management, smart street lighting, smart electricity management were implemented as a pilot (CORDIS 2017). In Stockholm, new technologies were used as an instrument and facilitator of transparency, accountability, participation, and governance principles. One of the projects developed to share democratic decision-making processes with citizens and the business world is a mobile application called "Make a Suggestion." The application was developed to increase the influence of citizens on city management. It is a platform where deficiencies in the external environment such as traffic, streets, and environment can be reported. With the study initiated by the Municipality of Stockholm in 2011, more than 100 data sets under 6 headings, including culture and archive, population, traffic, environment, geography, and citizen satisfaction, were made available to the public in order to promote innovation and transparency. With open data sharing via the website, one-third of the open data shared by the Swedish public sector is provided by the

city of Stockholm alone (City of Stockholm 2017).

Summary

Today, technology advances very rapidly and is integrated into human life. Computers that were not expected to enter homes before are now in the pockets of every person. Devices that are identical to each other over the internet collect and process a lot of data and communicate over the network. With the widespread use of the internet and the introduction of processing power to many devices around it, the concept of the internet of things has come into being.

Cities, where people live, have also been affected by the development of technology. Technology has been used for more livable, efficient, and sustainable cities and the concept of smart city has emerged. Resource efficiency and social sustainability reveal significant challenges for urban economies. Climate change and natural resource scarcity is an increasing concern for cities; taking measures throughout the city to alleviate climate change and emergencies has an important place in urban development strategies. This situation increases the interest in smart cities.

Smart economy (e-commerce and e-commerce, increasing efficiency), smart environment (renewable energy, measurement, pollution control and monitoring, renovation of buildings and social facilities), smart governance (the ability of the city to function effectively and effectively as an organism), concepts such as smart life (a culturally vibrant city with cultural opportunities) have become a part of the smart city with smart applications. With the increasingly widespread use of mobile devices and digital platforms, the concepts of big data and open data coming out with the collected data, the concept of the internet of things, three-dimensional printers, socially interactive robots, and drones, smart cities have become structures connected to a network.

Smart City strategies search and find innovative solutions such as interacting with different

actors, managing resources, and providing services. The components intelligently react to urban systems, and digital nervous systems. In this sense, they have led to the emergence of the city concept based on technology and innovation in the city by going beyond the classical city. State-of-the-art research focuses on cities learning to learn with advances in artificial intelligence and technology. Moreover, developments in nanotechnology address the creation of self-learning structures such as health, infrastructure, and transportation. Thus, in the future, it can be possible to ensure the continuity of systems that make city management directly smart, such as infrastructure, with social interactive robots. Some researchers are searching for ways to produce smart homes and therefore smart cities from seeds.

Smart Grid

Gülden Köktürk

Department of Electrical&Electronics Engineering, Dokuz Eylül University, İzmir, Turkey

Synonyms

Bidirectional decentralized power system; Electrical grid; Intelligent networks; Smart appliances

Definition

The network system, which is obtained by integrating computer and network technology of the twenty-first century into the networks that run almost the same way since the beginning of the twentieth century, is called “smart grid.” Smart grid is basically a distributed system formed by the integration of operation, knowledge, and telecommunication systems (Arnold 2011; Dinçer et al. 2011). Smart grids offer a sustainable, reliable, and high energy efficiency energy network by providing real-time bidirectional information transfer from energy generation to energy consumption at any stage (Thomas and McDonald 2015; Paul et al. 2014).

Smart grids are a fact that increases energy efficiency and effectiveness, decrease first investment, operation, and upkeep cost and where consumers also play an active role with new technologies (Çetinkaya 2012; Küçükbayrak et al. 1993). Some of the world-recognized and frequently used definitions of smart grids are:

- (i) According to US Department of Energy: 2030 network is conceived as a fully automatic power network which controls the endpoint with each customer by providing at all points bidirectional information and electric energy flow between power plant and end user's device.
- (ii) According to the European Technology Platform: A smart grid is smartly an electric network coordinating all users (generators, consumers, and users who can perform both operations) actions for sustainable, economical, and safety electric energy production.
- (iii) According to Electric Power Research Institute: Smart grid term corresponds to the modernization of the electric power system to optimize automatically, to safe, and to display the operation of all components connected with each other so as industrial customers, building energy management systems, energy storage applications, end users and their thermostats, electric vehicles, devices, and other household appliances by means of high energy lines in centralized and distributed production facilities.

In addition, all other definitions can be listed as follows:

- (iv) It is a power system consisting of several transmission and distribution systems that are efficient, reliable, depended on each one automation, and coordinated with each other.
- (v) It is a power system responding to the needs of the energy markets with production/transmission/distribution companies and self-healing in emergency conditions.
- (vi) It is a power system included a smart telecommunication infrastructure providing adaptive, credible, and promptly information flow, requiring growing digital economy and serving the customers with the number expressed in millions.

Power transmits another place produced in one place in alternative current systems. The fundamental of these systems is based on the fact that large production points until the last quarter of the twentieth century satisfy an

uncontrollable power of consumption under certain principles (Barai et al. 2015). In a network based on smart grid structure, the transmission and the distribution are provided to be within manageable rules with efficient resource utilization (Kanabar et al. 2012; Kuzlu et al. 2017).

Application Methods in Smart Grids

The electrical infrastructure in many regions of the world is interconnected, where large power plants are connected to each other through long transmission lines (Gonzalez-Longatt and Torres 2018). Instability occurring in case of system crash in any part of the interconnected network system causes to collapse the whole system and therefore energy interruption in other countries related to this country.

The effort to make them more efficient, safer, more environment-friendly, and more manageable with developing technological means of the electric network starting from the production stage of energy up to transmission, distribution, and consumption covering all processes is revealed as the "smart grid" concept (Hossain et al. 2013). This concept which appeared due to insufficient existing networks while intending full automation and high efficiency of networks is confronted as a new model combined of several technologies from communication to information technologies, control systems to semiconductor technologies (Borlase 2018).

The conventional and smart grid network systems are shown in Fig. 1.

Today, smart network applications can be grouped under three main headings:

- (i) Distributed generation applications: These applications are of great importance for energy efficiency, reliability, and use of renewable energy resources. Smart grids must provide the integration of a wide range of energy sources on the distribution network from small-scale power generation to high power plants. Thus, renewable energy resources will provide to expand up to the household level and to produce their energy. In this case, energy efficiency will increase by reducing production and consumption and transmission

Smart Grid, Fig. 1 The network system of (a) conventional, (b) smart grid (Erdoğan 2017)

losses. In a conventional network, the households of being static consumer level are expected the transformation to prosumers with distributed production opportunity.

- (ii) Distributed storage applications: It is aimed to store energy production excess stored in distributed storage systems to network and to use on condition that meets energy demand when necessary. Distribution of a very large storage system to the grid from high volume energy storage systems to the household storage system is very important for more effective usage of sources being energy continuity such as renewable energy resources.
- (iii) Demand side load management applications: Production demand balance and energy prices can be managed smarter in networks with distributed production and storage

facilities. Time interval where energy consumption is high is forced the network components. Although this problem is solved with the help of consumers, energy prices and energy efficiency can be increased. Energy production and storage strategies to be implemented on demand will significantly increase energy efficiency.

The abovementioned three applications are possible using effective communication and control tools. It should be real-time monitoring and control of the network for responding to the instantaneous changes and preserving the optimal work of power system. For this, the smart grid components should be acquiring to data recording, processing, and transmission. This too will be possible if the power components contain systems

(microprocessors) capable of communication and programming. Protocols to manage communication and interaction of these units (e.g., TCP/IP, ATM, SDH/SONET), communication infrastructure (e.g., modems, routers, wireless communication) and servers (application and databases), will be needed (Falvo et al. 2013).

Communication Systems in Smart Grids

Developments in today's wired and wireless communication technologies have accelerated the construction of the communication network of smart grids (Brandt 2015). In smart grid architecture, the communication requirement includes both communication of near field (building and on-site) and far field (local and intercity) (Emmanuel and Rayudu 2016). A smart power distribution infrastructure serving millions of users will need a high-speed data transmission infrastructure with high bandwidth to enable them to work and communicate in harmony. This infrastructure is now possible with both fiber technology and wireless communication facilities. The proposed main communication technologies by IEEE for smart grid applications are ZigBee, WiMAX, wireless LAN (Wi-Fi) technologies, GSM/GPRS, DASH 7, and communication (PLC) on power systems (Wang et al. 2011; Usman and Shami 2013; Nafi et al. 2016). The main advantage of smart grids is the establishment of a bidirectional communication network between consumers and energy sources. The bidirectional communication has become an important requirement in smart grid applications. The real-time communication capability of smart grids will be a milestone for the modernization of electricity networks. In this case, database centers, software based on manufacturer-consumer, distributed control units, wide-field applications will communicate through this infrastructure. This communication infrastructure can be built to accommodate a variety of communication paths, including broadband transmission and wireless technologies over the power line and fiber optic cable for today. The use of today's communication technologies in smart grids is summarized in Table 1.

The transition from today's vision to smart grid vision is a long-term change process, and this process of change brings along many social, technical, and economic challenges (Lin and Magnago 2017). Although it is difficult to predict the future of smart grids, it is obvious that it will add many benefits to the world at every stage.

Benefits of Smart Grids

Smart grid systems will increase efficiency using advanced level monitoring and maximize the potential and performance of assets. Losses in transmission and distribution are reduced with smart systems (Ma et al. 2016). Companies use resources more reliably and efficiently utilizing remote monitoring and control technologies. Due to digital communication, it is ensured that the system can work again as little damage as possible due to a mistake or interruption caused by human error or natural disasters in the smart grid. Moreover, it provides efficient use of fossil fuels with increasing the utilization of renewable resources. By providing consumers with better control of their electricity usage and consumption costs, electricity production companies provide better management of their high production demands and reduce their need for extra investment in high production demand. Considering the power networks, all points of the system ensure in a structure that vigilant, responsive, adaptive, cost-effective, environment-friendly, synchronous, flexible, powerful, and capable of connecting with any system. Smart grid procures the optimization of current control. It is agreed to the systems of alternative energy transmission and distribution as a digital version upgrade. Smart grids can be compatible with deferred or changed investments. Not only an intelligent transmission system can quickly isolate problem areas avoiding large-scale power cuts but also regulating and stabilizing the process after system crashes and accelerating the flow of energy.

The construction of the smart grid system structures shown in Fig. 1b will offer various opportunities and capabilities on a global scale in many areas. Opportunities in household scale are as follows:

Smart Grid, Table 1 The use of todays communication technologies in smart grids

Usage area	PLC power line communication	ZigBee	Wifi	WiMax	GSM and GPRS	DASH 7
Manufacture	Traditional	The researched systems that are not yet used but can be improved	The researched systems for use	The researched systems for use	System currently used	The researched systems for use

Flexible pricing system can be implemented with the smart meters. Thus, by their own preferences, the consumer will be able to shift their consumption with smart meters to the hours when the electricity price is low. If the consumers have the domestic energy storage units, the purchased energy with low price can be used in the high price time, or they don't have energy problems with short-term interrupts. This will gain significantly demand flexibility to network. Smart meters (AMR) supporting wide-field communication systems (e.g., GSM/GPRS, PLC) will provide an opportunity to remote management and testing of consumer information and of the energy system. The measurement, monitoring, and troubleshooting will carry out by remote control. Smart meters having the ability to communicating with wide area (GSM/GPRS, PLC, satellite communication) will allow providing multimedia services (Internet, telephony, etc.) of the houses via the power line. Smart systems will enable remote management of devices and communicate within the home devices themselves with narrow area in-house device communications (ZigBee, Wi-Fi, PLC, etc.) and ensure that smart home systems become more integrated and effective. Smart meters will be to facilitate the use and management of renewable energy systems and residential energy storage systems in homes. Bidirectional smart meters will be to contribute to both the consumer and the energy production by allowing the sale of the excess energy produced at home. Consumers are expected to have a productive consumer profile (prosumer) with these capabilities. Prosumers based on clean renewable resources will reduce CO₂ emissions and contribute to the production of environment-friendly energy. Excessed energy from renewable energy sources with the increase of electric vehicles can be used in transportation, and transportation by heavy pressure on the environment will be possible to realize a little more cost-effective and environment-friendly.

Opportunities in site/building are as follows:

With the integration of renewable energy sources into the microgrid, the energy dependence of the sites/buildings on the network can be reduced, and environment-friendly production and consumption can be supported. The management and control of in-site/building communication and site/building services (safety, irrigation, and in-house lighting systems) will be provided over the power distribution line (PLC).

Opportunities in the city are as follows:

Distributed sensor and control applications over the smart grid will provide the in-city services (lightning, irrigation of parks, safety, etc.) management, and automation. The gaining energy from solid wastes disposal facilities will use in the energy need of the in-city services over the smart network. The use of renewable energy resources in buildings will reduce the city's energy dependence to outdoors.

Opportunities in the country are as follows:

As a result of the widespread use of smart grids and renewable energy sources, dependence on oil, natural gas, and coal will decrease, and the weight of natural resources in satisfying the energy demand of countries will increase. Transmission-distribution losses and costs with on-site production and consumption using smart grids can be reduced. More efficient and reliable energy use will be possible. Demanded load management strategies and optimal consumption strategies can be implemented by the smart grid. Thus, excessive energy supply (overproduction) will be preventable, where energy prices can be kept at reasonable levels (Lund et al. 2012).

Opportunities in the global scale are as follows:

The usage of the renewable energy resources and smart grids will provide the major

contributions in increasing efficiency by on-site production and consumption, reducing the environmental pressure of human activity such as global warming and remaining more livable world. Smart networks connecting in global level will give flexibility to energy production and consumption and reduce conflicts and concerns based on energy sharing between countries. With the global smart grid integration, it will be easier for energy-producing countries to share their energy supply with the world. The socioeconomic effects of this possibility will make the world more global, and the borders of the country will become less important. Communication, remote measurement, and control facilities on a global scale will improve over the global network. This condition would simplify the operation of international scientific research and observation stations.

Summary

Nowadays, electricity reaches approximately 4.8 billion people, while more than 1.8 billion people have little or no access to electricity. Globally, more than 1.6 billion electricity meters have been installed at end-use points (homes, apartments, commercial buildings, industrial centers, factories, etc.). These meters measure the use of electrical energy to provide a turnover of more than 1 trillion dollars annually to the global electricity industry. There are around 43,000 medium and large power generation facilities that provide electricity to people in more than 200 countries around the world. These power plants transfer the generated electricity to the transmission lines through more than 120,000 amplifier centers with large and very large transformers installed. The distribution of electricity is started from approximately 200,000 distribution centers. Thus, any failure in such large grid systems can lead to major power outages. For example; On November 9, 1967, in the United States of America, New York, New

Jersey, New England, and Ontario regions, the electrical system failure affecting approximately 25 million people can be shown. Moreover, the illegal use of electricity brings considerable financial and hardware load to these systems and creates a damaging effect on the system. These and other such disadvantages reveal the necessity of better management of energy systems.

Consequently, smart grids being a nature-friendly technology, it plays an active role in fixed and traveling energy storage and scattered renewable energy sources. It is necessary to store energy for many reasons because the renewable energy sources are far away from consumption centers, not regular, and the weather forecast is not sufficiently accurate, also nowadays offer reliability of all modern energy systems, system stability, more efficient use of energy resources, minimization of transmission/distribution problems, and costs. Therefore, the three main objectives of smart grids are:

- (i) Preferable balancing offer demand side of the energy system, maximizing load factor preventing daily fluctuations in the load curve, for optimizing the network capacity
- (ii) Regulating the fluctuations in energy costs because of production and transmission limitations
- (iii) Constituting microgrids that allow for more distributed production (conventional or renewable) and energy storage in end user side

SMEs (and CSR)

Andrea Venturelli
Università del Salento, Salento, Italy

Synonyms

Small entrepreneurs

Definition

The Small and Middle Enterprises (SMEs) cover a central role within the worldwide ecosystems due to their wide diffusion.

The relationship between SMEs and CSR is strong because they represent the most common form of enterprises within the large part of the countries. Moreover, SMEs are typically characterized by the direct involvement of the local communities during their life cycle and a relevant influence exerted on the local and regional

economies. In this sense, although the physiological criticism related to the adoption of CSRs tools, the SMEs favor the diffusion of virtuous mechanism useful for the achievement of highest degree of sustainable development.

CSR in SMEs Strategies: Constraint or Opportunity?

During the last years, in order to cope with the modern globalized economy and the complex supply chain networks, SMEs have started to act sustainable and adopt CSR in their production activities. Several authors have analyzed the relationship between CSR and SMEs. Contrarily to MNEs and large firms, the debate has been characterized by different opinions about the effectiveness of the adoption of CSR practices in SMEs. Specifically, the academics have highlighted different implications and barriers related to the adoption of these practices.

According to Preuss and Perschke (2010), the approach to CSR by SMEs is different from the large firms. Specifically, the authors highlighted how the entire set of operations that describe a CSR practices is characterized by differences caused by the peculiarities of the SMEs such as the role of the ownership, the economic barriers, and the absence of market pressures. Also, being involved in less pressures at the regulatory and stakeholder level, SMEs tend to prioritize the adoption of CSR practices in their activities rather than allocating resources for the CSR communication. This behavior reveals a different approach of SMEs governance towards their stakeholders (Schons and Steinmeier 2016).

In these terms, Jamali et al. (2009) suggested how the contribution of SMEs is characterized by a more informal approach and by the absence of formalization. This evidence confirms the existence of different approaches to CSR. In fact, several authors have started to discuss about the existence of divergences between “walking” and “talking” about CSR practices (Schons and Steinmeier 2016). In particular, the “walking” identifies the actions that have been taken by companies to measure their CSR progresses

throughout years, while the “talking” comprehends the communication tools that have been adopted to disclose CSR information and progresses towards stakeholders.

However, the literature has highlighted the existence of positive externalities related to the voluntary adoption of these practices by SMEs. Specifically, an increasing number of academics have started to provide some insights both about the drivers that impact on CSR adoption and both on the subsequent financial performance (Vazquez-Carrasco and Lopez-Perez 2013).

The different involvement in market pressures impacts on the adoption of CSR in SMEs. Specifically, contrarily to the large firms, the determinant that impacts on CSR adoption is represented by the ownership characteristics. Literature reveals how the majority of business decisions in SMEs are taken by a single entity or a small group of subjects and the decisions are highly influenced by their personality traits and knowledge. This evidence is linked with the family nature of many SMEs (Sen and Cowley 2013). This evidence is linked with the family nature of many SMEs and the subsequent paternalistic mechanisms of their governance.

From this point of view, family SMEs adopt CSR in order to preserve and communicate the socio-emotional value that characterize the company (Drago et al. 2018).

On the other side, the adoption of CSR in SMEs can be also considered as a proactive coping mechanism. Specifically, by focusing on environmental, social, and governance dimensions, SMEs show their interest in listening their stakeholders request and related market pressures.

In addition, the introduction of CSR in SMEs represents a channel to communicate the investments in sustainability when green innovations are adopted by these companies (Cuerva et al. 2014).

Finally, regarding the financial performance, several papers have highlighted a positive relationship between cost reduction and CSR practices caused by the achievement of more favorable relationship with suppliers, clients, and financial institutions. Specifically, the adoption of CSR in SMEs allows to gain better financial conditions

from banks and opens a path towards public subsidies (Du et al. 2017).

The Link Between SMEs and Sustainable Development Goals

According to World Bank, the SMEs represent over the 90% of the worldwide business and the 50% of the worldwide employment. Furthermore, they contribute to the 40% of the national income (GDP) in developing countries. The evidence shown above highlights the strategic role covered by this type of enterprises for the achievement of the Sustainable Development Goals (SDGs). The strongest connection between SMEs and SDGs is represented by the exigence to create new job position in developing countries. In this sense, the SMEs represent a central item within the strategies inspired by the “*Leaving no behind*” principle. In fact, contrarily to MDGs, one of the main innovations of the Agenda 2030 is represented by the direct involvement of the private sectors. Specifically, the CSR in private companies is going through different changes, and the contribution on the pursuit of the SDGs represents an occasion to improve collaboration among companies (Scheyvens et al. 2016).

The Agenda 2030 underlined the need of a direct involvement of private sector. In detail, the United Nations stated: “*no one will be left behind. Recognizing that the dignity of the human person is fundamental, we wish to see the Goals and targets met for all nations and for all segments of society. And we will endeavor to reach the furthest behind first.*” In fact, as evidenced before, the SMEs represent typically the main job provider in developing countries. Furthermore, the evidences collected by OECD reveal how SMEs contribute positively to the GDP even in developed countries such as the UK and the Greece.

The main SDGs that required the direct involvement of the SMEs are represented by SDG8 (*Promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all*), SDG9 (*Build resilient infrastructure, promote inclusive and sustainable*

industrialization, and foster innovation) and SDG10 (*Reduce inequality within and among countries*). The SDG8 required a direct involvement of SMEs within the target 8.3 who required to the Governments to promote policies in order to favor the growth and the diffusion of the SMEs within the countries. The contribution of the SDG9 is represented by the requirement in target 9.3 of policies inspired by the exigence to allow SMEs to engage with financial institutions in order to support their growth. Finally, the contribution of SDG10 consists in a set of targets oriented to the improvement of the work condition of the SMEs.

Conclusion

The achievement of the SDGs requires a direct involvement of the private sectors. As evidenced by the World Bank, the SMEs cover the 90% of the entire worldwide economic systems. In this sense, it appears obvious that the achievement of the SDG could not be unrelated to the direct involvement of the SMEs. Although the CSR has been wide analyzed by academics during the last decades, only few studies have analyzed the managerial implications related to the adoption of CSR practices by SMEs. According to this evidence, the future research could be addressed to fill these gaps in order to provide to policy makers evidence-based results useful for the definition of new policies to sustain the SDGs.

Social Acceptance

Adriana Paliwoda-Matiolańska
Cracow University of Economics,
Kraków, Poland

Synonyms

[Community acceptance](#); [Public acceptance](#); [Public attitude](#); [Social environmental impact of project](#); [Socioeconomic impact](#); [Socio-political acceptance](#); [Stakeholders acceptance](#)

Definition

Social acceptance is the attitude of society or a specific social group to a specific problem arising from the redistribution of costs and benefits.

Social acceptance can be analyzed from two perspectives. The first one, and the majority of the research is focused on this approach, understands it as an attitude of public opinion or a specific group to a particular problem. Mostly it focuses on positive and negative strategies with a concentration of nature, structure, and level of objection. Among this approach, we can distinguish a narrow and broad path. Narrow criteria to social acceptance are very often centered on frequent problems referred to as NIMBY (not in my backyard) point of view. The objection is then structured around the locations of particular projects. In particular the projects of the infrastructural nature, close to the place of residence of the local community. Social acceptance is understood by terms of any action taken by residents or as a lack of opposition. The in-depth approach includes the spectrum of geographical, institutional, or cultural aspects. The starting point is the inclusion of the local community

perspective. The most important is transparency of action, based on the fact that the local community can co-participate as stakeholders in developing the infrastructure and whether they can trust investors, especially if they come from outside of the local community. In this understanding, social acceptance is gaining special significance, especially during the time of digitalization of the economy, social media, and the Internet being used for authorization of stakeholders and monitoring of democracy and civil rights.

The second approach indicates that social acceptance is the result of a dynamic and multidimensional process in which the project itself, opinions of stakeholders, and the context of the undertaken actions are mutually supplementing. The focal points are that the acceptance of local communities is related to the feeling of justice. It comes as a result of both costs and profits from both project implementation processes and the desired results of its implementation. The focus is on cost and benefit distribution. Therefore social acceptance is defined as a set of outcomes and aspects that leave local at least as well off as they were before the project. It is understood as a set of desirable results that leave the local community in the situation not worse than before the project. According to this approach, we can distinguish three dimensions of social acceptance (Wüstenhagen et al. 2007): (1) sociopolitical acceptance (technologies, policies, institutional changes, policymakers, the public, key stakeholders), (2) community acceptance (place attachment, landscape identity, fairness of process, residents, local authorities, trust), and (3) market acceptance (consumers, investors, green tariffs, intra firm, incumbents, new parties).

Summary

Social acceptance examines the public's attitude toward a specific problem by analyzing the perpetrators and losses that a particular social group suffers as a result of implementing a particular project. Sociopolitical, community, and market dimensions create a base for the analysis. Social

acceptance should be the result of achieving balance in the abovementioned areas that guarantee that a particular status of a social group will not be worse after project implementation than before its start.

Introduction

“Social Accountability International (SAI)” is a global nongovernmental organization that aims to enhance human rights at work. In order to achieve its mission, SAI in a multi-stakeholder approach created the SA8000® Standard for fair labor practices. This standard helps to implement international standards on decent work, which meet the requirements of the “Universal Declaration of Human Rights” and “International Labour Organization (ILO) conventions.” It also reflects and complements national and international labor laws. The standard is being used in over 4,000 companies in more than 62 countries and 56 industries (last updated: May 3, 2019). SAI regularly revises the SA8000® Standard in order to respond to upcoming social and human rights issues. The last time that the standard was revised was in 2014.

SAI is responsible for the development, revision, and publication of SA8000®. It is not accountable for the auditing and certification itself. These services are carried out independently of SAI by accredited institutes. Besides the standard itself, SAI provides guidance on the standard’s implementation and determines the program’s auditing methodology. Additionally, SAI offers benchmarks and reports, e.g., on living wage and conducts trainings for auditors of the SA8000® Standard as well as for companies that aim to improve working conditions in their global supply chain.

Social Accountability Accreditation Services (SAAS) is a department of SAI that develops evaluation and quality assurance systems through third-party assessment and accreditation services. SAAS maintains its own independent decision-making process for its accreditation systems. All certification bodies that conduct SA8000 audits have to apply to SAAS for accreditation.

The History

In 1969, Alice Tepper Marlin founded a nonprofit organization in order to further investigate

“corporate social responsibility”: The Council on Economic Priorities (CEP). CEP offered monthly newsletters on research reports and provided studies on corporate social responsibility for investors (such as global corporate ratings) and published corporate reports as well as several guidelines and books, such as *The Better World Investment Guide: One Hundred Companies Whose Policies You Should Know About Before You Invest Your Money* (Hall 1991) or *Shopping for a Better World: The Quick and Easy Guide to All Your Socially Responsible Shopping* (Hollister et al. 1994). Additionally, CEP awarded a corporate responsibility prize, started the Campaign for Cleaner Corporations, and provided Corporate Environmental Data Clearinghouse (CEDC). A large variety of researchers worked together on the CEDC in order to analyze the environmental policies and performance of corporations. Reports based on the results of the analysis provided the investment community with unbiased, comprehensive, and concise information on issues regarding the corporate responsibility. In its work CEP focused on several topics referring to the responsibility of companies:

- “the environment
- women & minority advancement
- disclosure of information
- labor relations, family benefits
- charitable giving, community outreach
- military contracts, nuclear power
- tobacco, product liability, animal testing
- South Africa and Third World concerns.” (O’Brien 1998, 11)

Newly discovered facts on inhumane working conditions in developing countries caused a greater public dispute on social responsibility. In reaction to this public concern, CED founded the “Council on Economic Priorities Accreditation Agency (CEPAA)” in 1997.

CEPAA’s remit was to set up a universal standard for responsible employment practices in manufacturing industry. It took nearly a year until the advisory board published the final draft of SA8000® Standard on decent work in 1998. SA8000® Standard is a voluntary multi-industry

standard for companies that are interested in independent third-party certification regarding decent work in their own facilities and in those of their business partners and salesmen. The advisory board, consisting of 25 people of different backgrounds, such as businesses, trade unions, and nongovernmental organizations, designed the SA8000 to be compatible with the ISO 9001 quality standard. Now, as it has been finalized, the advisory board regularly revises the standard to ensure its topicality. The latest revision took place from May 2013 to February 2014 so that the current version of the standard is the “SA8000: 2014.”

In 2000, CEPAA was renamed into SAI, a new affiliate of CEP. CEP itself doesn't exist anymore (closed in 2001), but SAI as a former entity of CEP still carries on publishing and revising SA8000 and its supporting documents and offering instruments that help organizations to maintain and continually improve their social performance.

Definition: Mission, Objectives, and Focus Areas

SAI's mission is to advance human rights at workplaces in order to contribute to a world where workers, businesses, and communities thrive together. To achieve its mission, SAI publishes and reviews the SA8000® Standard on decent work, which focuses on nine “key areas”:

- “Child labour
- Forced labour
- Health and safety
- Freedom of association and collective bargaining
- Discrimination
- Disciplinary practices
- Working hours
- Compensation
- Management systems.” (SAI 2019)

“Management systems” (the last of the nine key areas) treat structures and procedures that

companies must adopt in order to ensure periodical management reviews regarding the standard.

SA8000® comprises existing international agreements, such as the Universal Declaration on Human Rights, the International Labour Organization conventions, and the UN Convention on the Rights of the Child. But it also sets new standards governing workers' rights, like working hours per week, which are not allowed to exceed 48 h or 6 days a week.

Additionally, SAI provides background information, explanations, and supporting documents regarding the standard, which help organizations to develop their social performance continually. Aspects include capacity building, stakeholder engagement, collaboration between buyers and suppliers, and the development of instruments in order to push ongoing improvement. Four strategic programs offer companies an easier approach toward decent work:

- One of those programs is the Social Fingerprint® program, which is supposed to support companies to understand and measure their social impact and to improve it. The program includes ratings, trainings, and toolkits designed to break down the management system concept into component processes that systematically ease the company's improvement (and the one of its suppliers).
- Another strategic program is “TenSquared,” which was designed by SAI in cooperation with the Rapid Results Institute (RRI) and The Walt Disney Company in order to enhance health and safety at workplace. For that reason, SAI or the RRI identifies shared interests of workers and managers and translates them into action within 100 days. SAI and RRI cooperate with local organizations in the country of implementation, which helps to correspond to specific challenges.
- SAI supports and promotes “living wage.” Therefore, SAI, as a member of the Global Living Wage Coalition (GLWC), developed the “Anker methodology” – a tool that helps to estimate the wage for a basic-but-decent

lifestyle for workers and their families in a specific place.

- The last of the four strategic programs is the “International Recruitment Integrity System” (IRIS). It is a social compliance scheme to improve ethical international recruitment. It was developed by the International Organization for Migration (IOM) in cooperation with a bunch of partners, including SAI. The IRIS Standard (published and reviewed by IRIS) sets a benchmark for ethical recruitment. With the help of the IRIS standard, companies are able to establish a voluntary certification scheme for ethical labor recruitment and a compliance and monitoring mechanism.

Besides its strategic programs, SAI offers trainings and capacity building services on human rights at work (face-to-face as well as online). The auditor training course covers information on the SA8000® Standard as well as auditing techniques and general information regarding the auditing process. All SA8000® auditors have to pass the “basic auditor training.” Those who aim to become lead auditors additionally have to pass the “lead auditor training.” Even though both courses are designed for certification bodies and internal auditors, they are also relevant to purchasing agents, managers, and employees, who are supposed to audit any other decent work standard.

Furthermore, SAI offers trainings with a specific focus in its Professional Development Series, e.g., “Management Systems for Social Performance” or “Building Internal Social Performance Teams.” These courses are designed for sourcing personnel, corporate compliance managers, suppliers, and auditors that like to better themselves and keep informed. The custom training program is made for companies that aim to improve their performance or want to expand their control of subcontractors or suppliers. It covers a variety of topics in order to meet companies’ individual needs. SAI helps to identify these specific needs and develops a strategic plan and training.

Finally, SAI offers companies two ways to show their commitment to social responsibility: via certification and/or via becoming a corporate member of SAI. All corporate members are supposed to place the following public statement on their website:

As a Corporate Member of SAI, we share the mission to improve working conditions in our supply chain, in accordance with performance criteria based on relevant ILO conventions and national law, utilizing management systems and multi-stakeholder dialogue.

There are three different types of corporate membership depending on the level of engagement: supporter, explorer, and signatory. SAI offers most services to those companies that are at the signatory level and fewest to those on the supporter level. Regardless of the level, all companies have to support the abovementioned statement. Further, they ensure to use a management system approach to enhance their social performance. Moreover, they are supposed to join the “Social Fingerprint® Supply Chain Management program” which takes place annually and have to use all services provided by SAI.

Structure of Governance

SAI is a charitable 501(C)(3) organization located in the United States of America. It is based in New York and governed by a board of nine directors chaired by Dan Henkle, the former president of Gap Foundation and senior vice president of Global Sustainability at Gap Inc.

An advisory board supports SAI’s work with its professional expertise. It consists of two different types of members: those who are affiliated with business (eight members) and those who are affiliated with NGOs, trade unions, socially responsible investing, and government (seven members).

Retired SAI Advisory Board members are united in the Founders’ Committee. The Founders’ Committee members are allowed to

participate in SAI Advisory Board's activities, such as meetings, in which they may take part as nonvoting members. Founders' Committee members include Tom DeLuca (Chair), Dr. Morton Winston, and Achim Lohrie, among others.

An annual conference of all board members and directors fosters the exchange of knowledge regarding CSR practices of different stakeholders.

SAI finances itself either by single corporate/private donations or via its corporate memberships and training programs.

Summary: Major Accomplishments/Contributions

More than two million workers experience concrete benefits from the implementation of the SA8000® management system. More than 4,000 facilities have been certified across 62 countries and 56 industrial sectors (last updated: May 3, 2019). Implementing SA8000® and/or participating in SAI's corporate program gives confidence to all employees and managers regardless of their position within the company's hierarchy and supply chain. It leads to a greater awareness about core labor rights and therefore enables workers to claim their rights, such as organizing trade unions or bargain collectively.

Not just workers and managers benefit from SAI's work but also consumers and investors, to whom credible assurance for ethical purchasing decisions is offered.

Finally, it helps companies to demonstrate their dedication to decent work. Keeping in mind that the standard is regularly revised, it enables companies to face new and emergent social and human rights issues. Dealing with SAI's topics enhances the corporate reputation and eases the management of the supply change management. Additionally, it helps to improve employee recruitment, retention, and productivity.

Companies that are SA8000-certified meet most of the requirements of "The Foreign

Trade Association's Business Social Compliance Initiative (BSCI)." Therefore, they shall add the information that they are certified to the BSCI IT platform in order to avoid duplication.

Definitions and Description

Social capital is an approach that considers the actions carried out by policymakers aimed at finding efficient, but not necessarily economic, solutions to social problems (Portes 1998).

Social capital differs from human and economic capital mainly in its tangibility. While human capital is based on education, training, and experience (Leitão and Pereira 2022), which are transformed into competencies, skills, and knowledge that entrepreneurial individuals possess (Gianesini et al. 2018) and that are recognized in the form of educational achievements, economic capital is measured in monetary terms.

The most insightful approaches to interpreting social capital have been proposed by James Coleman, Pierre Bourdieu, and Robert Putnam. The latter author's approach is indebted to Coleman to some extent, while Bourdieu's concept differs significantly from both.

Bourdieu (1980) presented a seminal analysis of social capital, noting that this type of capital comprises the sum of current or potential resources associated with the possession of a network of institutionalized relationships (Bourdieu 1985). His approach to this concept is instrumental and focuses on the benefits that accrue to individuals through participation in a group and the intentional construction of sociability to create this resource. According to Bourdieu (1985), actors can use social capital to increase direct access to economic resources, including subsidized credit, investment tips, and protected markets. In addition, they can build their cultural capital through contacts with specialists or experts (i.e., embodied cultural capital); alternatively, they can associate with organizations that provide them with valuable credentials (i.e., institutionalized cultural capital).

A less central source of interpretation is found in Loury (1977, 1981), who argues that orthodox economic theories focus exclusively on individual human capital and make the level of competition in the marketplace dependent on educational attainment alone. The idea of legitimacy, which any individual can be legitimized by his or her abilities, contrasts with the evidence suggesting that no one is able to do so by ability alone.

Loury (1977, 1981) laid the foundation for the subsequent work of Coleman (1988), who outlined the importance of social capital in promoting human capital. Coleman (1988) defined social capital as a mixture of two crucial elements, namely, social structures and individual or corporate actors. Thus, the former facilitate social action, while the latter enable that social action by ensuring reciprocity and the enforcement of norms in the group. The motivations of both individuals and firms deserve further research efforts, as they form the core of social capital. The contribution coming from Coleman (1988) has the undeniable value of introducing and popularizing

the concept of social capital, highlighting its importance in the acquisition of human capital, and showing some of the mechanisms by which it comes about (Portes 1998).

The theoretical foundations contained in Coleman (1988) formed the basis for the formulation of social capital provided by Putnam (1993a). Following Putnam (1993a), social capital is a factor that facilitates interpersonal cooperation in cities, regions, and countries and can be used to combat many social disorders. In addition, Putnam (1993b) advocates that this type of capital includes all the features of social organizations (e.g., networks, norms, and trust), which facilitate action and cooperation for the common good. Putnam (2001) extends these characteristics to include the connections between individuals, social networks, and the norms of reciprocity and trust that result from interactions among them.

Another feature commonly used to describe the concept of social capital is the potential reduction in transaction costs that results from better coordination (Fukuyama 2001). In this regard, social capital expands networks and deepens their cohesion. Therefore, there is a positive relationship between social capital and outcomes expressed through civic engagement, development, and democratic participation.

Putnam (2001) goes beyond a mere relationship to a particular causality in which social capital is a determinant of civic participation and development. This has led to a great deal of effort by political and economic researchers devoted to the causally link leading social capital to every positive and advancing component of a sustainable social order.

The last words are dedicated to Becattini (2004), a prominent political economist who emphasizes the Marshallian sense of industrial concentration of productive activities and positions social capital as the true anchor of the ecosystemic relationships built by the entrepreneur and the networks of formal and informal institutions at the level of the territory and Marshallian industrial districts that contribute to the reduction of both switching and transaction costs. There is an opportunity to revisit these industrial districts and deepen

the role of social capital based on the connectivity of global networks of people and innovation activities focused on fostering new digital and sustainable ecosystems.

Summary

The interpretation of social capital is a major challenge, as is evident from the contributions of the maestros of the social capital theory discussed and presented here. Access to the conditions of social capital, the development of social capital, and the effectiveness of its application, both in activities in society, in the economy, and in the policy arena, are crucial steps to ensure a better interpretation of the increasing importance of this type of intangible asset. In this regard, the barely reconcilable roles of social structures and networks, as well as family and interpersonal relationships, deserve to be the subject of further in-depth multidisciplinary research and targeted policy action. In addition, the nature of the role that social capital plays, for example, as a facilitator or mediator with respect to the relationships between motivations and exchanges, including reciprocity, expectations, and norms of enforcement, on the part of participating groups (i.e., formal, and informal) deserves more attention from scholars, policymakers, entrepreneurs, and social innovators. In the Coleman's (1988) tradition, social capital is based on three main components, namely, owners, sources, and resources. The distinction between tangible and intangible capital and the exploration of cognitive social capital at the individual, institutional, or organizational level should be on the agenda of future research and policy. Positioning social capital as a facilitator of social action and collaboration for mutual benefit should be considered a priority to pursue. In this context, social capital has a key role to play in fostering mutual trust and social participation and thus in ensuring the quality of democracy. Moreover, social capital can help reduce transaction costs and provide the necessary link between digital and sustainable ecosystems that serve the common good and sustainable progress.

Definition

The historical evolution of the social capital (SC) conceptualization is rooted in the sociological field, appearing in the second half of the twentieth century.

The approaches developed on the SC concept are diverse but converge on its multidimensionality and a general meaning: individuals and groups gain access to resources, benefits, and opportunities through their human sociability. Accordingly, SC comprises several elements, such as social relations, social support, or social cohesion, that are not interchangeable with the whole term. Hence, SC in organizations deals with intangible assets and does not exist and function except in a specific context (Bourdieu and Wacquant 1992).

Recently, the interest in SC measurement has gained momentum in the management and accounting literature in relation to sustainability reporting initiatives and the UN 2030 Agenda. By the way, there are no universally accepted standards for measuring SC, since the measurement approaches depend on the diverse SC conceptualization, the context of investigation, and the social

setting. To date, the present SC disclosure in organizations mainly deals with narrative descriptions.

Origins and Main Contents

Bourdieu, Coleman, and Putnam authored the most shared conceptualizations of SC.

Bourdieu (1980) defines the SC as the potential and concrete resources an individual derives from belonging to a stable network of social connections. Coleman (1988) introduces the economist's principle of rational action and defines the SC as a collective asset that facilitates some actions to fulfill individuals' interests, but the wider group benefits from the outcome. As for Putnam (1993, 2000), SC is a collective feature composed of trust, shared norms, and civic sense, realizing action and cooperation for mutual benefit. The latter definition corresponds to the one most applied by global institutions in highlighting the importance of SC in creating value for individuals, institutions, profit and not-for-profit organizations, and communities (e.g., Lin 2001).

However, SC can also have adverse functions, effects, and consequences. For instance, it can lead to the dissemination of incorrect information and the adoption of unhealthy lifestyles or illegal behaviors (e.g., Banfield 1958; Canestrini 2016).

Recently, SC has received interest in sustainable management and accounting literature. The SC is a heuristic concept for sustainable management and accounting field because, among the others, it allows the understanding of power and inequality distribution and how people access resources, benefits, and opportunities as well as economic capital, increase their cultural capital, develop human capital, or acquire influence without employing economic resources.

Adding to the previous, in the scope of entrepreneurship literature, following Aldrich and Zimmer (1986), the founders of new ventures use their SC including their own personal networks from which they will be able to select the needed workers. This option based on SC is justified by Aldrich and Langton (1997), who advocate that the founders of new ventures prefer employees with whom they can share

responsibilities and previous co-working experiences in the early stages of the firm's development.

Previous research has claimed the crucial contribution of SC to individuals, organizations, and communities. Among the others, Ostrom (1999) argues that SC helps achieve more security and peace and lower transaction costs through helpfulness and solidarity, with no increase in gross domestic product (GDP). Hence, sustainability reporting initiatives of international institutions such as those of the International Integrated Reporting Council (IIRC), the World Business Council for Sustainable Development (WBCSD), and the Global Reporting Initiative (GRI) have flourished providing attempts of SC measurements. Indeed, organizations disclose the SC in their reports, along with other forms of capital (e.g., IIRC 2021).

In terms of entrepreneurial endeavors, Leitão and Pereira (2022), when assessing the sustainable growth of start-ups, demonstrate that start-up founders when deciding to add teammates to the new venture look for people highly skilled, trained in the same target industry, using their SC based on connections established in previous co-working experiences.

Furthermore, within the UN 2030 Agenda, SC intervenes on two levels (e.g., Siboni and Rignanese 2022). At the general level, it embodies collective action to achieve sustainable development. Mutual trust and solidarity performed by people living and working in a society develops cooperation and allows that social context to function effectively, while, at the particular level, it represents the key factor in pursuing Goal No. 17 (Partnership for the Goals).

Proposals for Measurement

There are no widely accepted, standard, or comparable approaches to measuring SC. This is mainly due to the abstraction of the concept. Hence, it cannot be measured directly but requires an operationalization process. Such a process follows the theoretical underpinnings adopted to interpret the SC. Still, an agreed definition of the concept is lacking in the literature. Furthermore,

the SC changes from the context of investigation as it depends on the social setting and varies in time and place.

The SC that institutions, as well as profit and nonprofit organizations, disclose according to the criteria and guidelines contained in the reporting frameworks is a compound of determinants. Usually, it considers elements such as (1) social networks within the organization and relationships between stakeholder groups and the community; (2) shared rules, behaviors, and values; (3) trust, reciprocity, and commitment developed; and (4) reputation and legitimacy to operate in a given social context. Consequently, SC consists of intangible assets, information, and knowledge that increase individual and collective well-being and protect benefits for external stakeholders. SC academic disclosure found in the literature is often narrative and varies according to the context and approach to the SC (Adams 2020).

SC can be focused from different levels of analysis, distinguishing a heterogeneity of dimensions and subtypes. Existing attempts to measure SC are based on a specific theoretical understanding of the concept and a particular level of analysis. Accordingly, such attempts have used proxies or indicators and identified and measured the determinants or manifestations from which SC can be inferred.

Some measurement solutions have focused on the social level at which the interaction occurs, which refers to different types of SC network ties. Hence, it is possible to consider the SC developed among individuals within homogeneous groups (bonding SC), among people belonging to different social groups crossing sociodemographic and organizational lines (bridging SC), and among people who have vertical connections to formal institutions and political or economic leadership (linking SC).

Another approach to SC articulates the configuration and pattern of connections into structural, cognitive, and relational dimensions of SC (e.g., Nahapiet and Ghoshal 1998; Subramaniam et al. 2013):

- The structural dimension considers the network of people known to an individual from which she/he can access benefits. This network

is characterized by elements such as the number of bonds a person has, closeness or social distance between people, frequency of contact, and hierarchy between relations. The study of structural SC applies a network approach to tangible relationships within a specific social context.

- The relational dimension considers the nature and quality of the relationships. A relationship is based on interactions between individuals over time through which interpersonal trust, obligations and expectations, respect, and identification with other individuals are established. It is tangible by detecting the flow of resources reached through the interaction in social relationships articulated by nature and quality.
- The cognitive dimension is the set of shared values and norms that define ways of acting appropriately in a social context, predisposing people to mutually beneficial collective action referring to shared objectives. Therefore, it relates to cognitive schemes, language codes, and systems of meaning that provide the basis for communication and create narratives to interpret a shared reality. This dimension of SC manifests itself in using specific languages and codes.

Moreover, depending on the level of analysis, SC development can be focused at the micro (individuals) or meso (group or organization) or macro (community or national context) level. Furthermore, issues related to actors developing SC, substance/form that SC takes, as well as outputs, and outcomes it generates are other levels of analysis for SC understanding.

Often, the empirical research and practical applications of the concept intersect the various types, dimensions, and analysis levels described above, applying multi-method and multilevel strategies (e.g., Van Deth 2003). Moreover, they include potential indicators for one or more subtypes of SC, such as the structural dimension to detect SC at the meso level; the observation of bonding, bridging, and linking relationships within the relational dimension; and the cognitive dimension involved at the macro level. In

addition, in literature, the SC has been variously described and measured starting both from the elements that indicate its source or determinants and from those that represent outcomes, sometimes with a mixture of these components.

Examples of Measurement

Within the rich tradition of SC measurements, there are some precedents suitable for sustainable management. Each example operationalizes a precise definition of the concept and underpins one or more types of SC (bonding, bridging, and linking SC), dimensions (structural, relational, and cognitive), and level of analysis (micro, meso, and macro). The following are worth mentioning, from the tools measuring the SC worldwide to those pertaining to organizations.

The most recent tool with the broadest scope is the World Social Capital Monitor, WSCM (<https://sustainabledevelopment.un.org/partnership/?p=11706>), created by the UN Sustainable Development Group and operative since 2016. The WSCM measures SC within the UN SDG partnerships examining the social goods as an interdisciplinary nonmaterial asset for SDG achievement. It consists of an online self-completed questionnaire containing eight questions concerning climate, trust, measures to finance public goods through austerity and taxes, local investments, availability, friendliness, and hospitality. Therefore, the WSCM elaborates some indicators applicable to developed countries as well as to poor rural areas, among the illiterate and in conflict regions, creating timelines by city, region, and country to alert, make forecasts and benchmarks, and allow comparisons between 141 countries. The WSCM's ultimate purpose is to encourage SC awareness and include SC in other indexes, entering among the first non-material indicators collected from citizens' inputs.

The WSCM was informed based on other experiences, such as the World Bank Integrated Questionnaire for the Measurement of Social Capital – SC-IQ (Grootaert et al. 2004). The World Bank developed the SC-IQ, grounding it on the Social Capital Initiative created in 2002

through 12 studies in Africa, Asia, and Latin America (Grootaert and van Bastalaer 2002a, b), and applied it in Albania and Nigeria. The SC-IQ aims to demonstrate the SC impact on development outcomes at the national level, especially in developing countries. The SC-IQ defines the SC as the glue that holds societies through internal social and cultural coherence, norms, and values that govern interactions among people and institutions. It addresses six dimensions of SC: groups and networks, trust and solidarity, collective action and cooperation, information and communication, social cohesion and inclusion, and empowerment and political action. It generates quantitative data through a questionnaire and individual interviews, allowing in-context adjustments and modifications to the survey instrument.

The Social Capital Assessment Tool (SOCAT) is another tool offered by the World Bank (Grootaert and Van Bastelaer 2002a) for SC measurement as the previous one, but focusing on communities and organizations. The SOCAT integrates quantitative and qualitative data on SC surveyed by focus groups and a community questionnaire on community assets and governance, collective action, the density of local organizations, and the relationships among organizations and between organizations and the community, developing around 100 correlation items.

With specific reference to organizations, the Network for Business Sustainability, NBS (www.nbs.net), developed a tool in 2014 for decision-making and reporting. It defines SC as relationships inside and outside an organization that allows access to resources, knowledge, or information and holds internal and external forms. This approach articulates the SC into three dimensions – social networks, trust and reciprocity, and shared norms and values – to which it associates specific measures and tools. Specifically, organizations survey the different SC characteristics according to these dimensions through questionnaires, focus groups, and social network analysis. Existing instruments for surveys such as the World Bank's SC-IQ mentioned above can be adapted for the purpose, as did two organizations

in South Africa (a platinum industry and a freight transport company) for SC understanding and management.

Finally, the SC can be applied to develop research and measurements within the management and accounting field by crossing it with other constructs, such as the Millar's work (2021), which combines concepts such as cultural capital, SC, and habitus to explore financialization, inequality, and life in the fund management sector.

Summary

There are many definitions of the concept of SC. A high level of consistency in sustainable management and accounting literature agreed in considering SC as the resources, knowledge, and information that an individual, group of people, or an organization accesses through social networks within and between the organizations, community, and institutions.

The approaches developed to measure SC follow the conceptualization adopted, the type of SC (bonding, bridging, and linking SC), the dimensions of SC (structural, relational, and cognitive), and the level of analysis (micro, meso, and macro) considered. Furthermore, the SC measurement varies depending on whether the study focuses on the form it takes and what kind of outcomes it generates. Several examples of applications are provided.

Medicine, Rady Faculty of Health Sciences,
University of Manitoba, Winnipeg, MB, Canada

Synonyms

Community services; Government-provided services; Social service; Social welfare; Social work; Support services

Definition

Social care relates to the care by public or private companies for people in society who need special help such as help with washing or eating to live comfortably. In general, the term social care or its frequently used synonyms social work or social welfare also refers to all kinds of personal care and other practical assistance that contributes to improving the quality of life, subjective well-being of individuals, groups, and communities in need or at risk of being in need. Usually, these groups include children, young and older adults, individuals with mental or physical disabilities, individuals suffering from alcohol and substance abuse, and people of ethnic and racial minorities, among others. Social care is intended to promote independence, self-development, help with daily living activities, and personal care. Thus, the concept of social care is broad and provided by both formally (public, private agencies) and informally (family, kin, friends). Usually, formally funded services are based on the assessments done by a social worker and other professionals involved in the care plan. Regardless of how each agency funds and provides its services, gaps and barriers exist in the delivery of services. Research has shown that gaps and barriers in service delivery can be improved through integration of health and personalized social care. The following sections summarize the need, integration, and personalization of social care.

Need

Need for social care is diverse and arises due to illness, disability, social disadvantages, injustice, and vulnerability to the negative environments, among others (WHO 2018). Also, individuals in certain age groups such as older adults and children are vulnerable to illness and negative environments than others. Some of these negative environments to which older adults and children are vulnerable include homelessness, unhealthy living conditions, susceptibility to communicable and infectious diseases, abusive treatments,

etc., among others. Social care need for *older adults, young adults and other individuals, children, and families and care givers* are described below.

Older Adults: Worldwide, 125 million people are aged 80 years or older (WHO 2018). The pace of population aging is increasing and it is estimated that by 2050, one in six people in the world will be over the age of 65, up from one in 11 in 2019 (United Nations 2019). Although, older adults bring opportunities and contribute to their families and society as a whole, the extent of their opportunities and contribution depends on their health. Older adult's health is a variable and is influenced mostly by their physical and socioeconomic environments and their genetic inheritance. Therefore, an older individual from a disadvantaged background is more likely to experience poor health and be in need of health and social care services. There is little evidence that older adults today are experiencing better health than their parents (WHO 2017a). In fact, older adults with multiple health problems and frailty are growing (Chi et al. 2011; Smith et al. 2012), requiring the most extensive support including personal care such as washing, feeding, and so forth in addition to the supervision of their medical conditions. Thus, care and services required by older individuals are diverse in terms of their health, living arrangements, income, and other resources that determine the extent of social care they need. Most of the developed countries have their own systems to provide some kind of long-term care services to the older adults; however, the system of providing long-term care services to older adults may not exist at all in some developing countries. In this context, it is worth mentioning that the number of older people needing support for activities of daily living in developing countries is estimated to quadruple by 2050. This situation implies that in the twenty-first century all countries will have to build an integrated system of long-term care either from the scratch or by remodeling the existing one to a broad-based and whole system approach that maximizes older people's functional ability and supports their autonomy and dignity (WHO 2017a).

Young Adults and Other Individuals: The social care need for adults below 65 years is also increasing. Research has shown that social care costs will rise significantly not only because people are living longer, but also because many young individuals are developing chronic diseases such as diabetes, pain, osteoarthritis sensory impairments, and disabilities arising from chronic diseases, accidents, vision loss, and amputation, among others (Marengoni et al. 2012; WHO 2017a). Therefore, based on the severity of illness and disability among these people, an array of care and support services is required to maintain their autonomy and dignity and ease other activities of their daily living. In addition to young adults, other individuals or groups who need care and support to improve their quality of lives are homeless people, people with mental health problems, learning disabilities, alcoholism, and substance abuse. Apart from self-harm, mental illness, alcoholism, and substance abuse contribute to domestic violence, abuse, and may cause serious harm to people and communities as a whole. Therefore, to prevent violence and harm, these individuals may need specialized and coordinated care provided by health care or other agencies either at home or at hospital or correction and rehabilitation facilities, among others.

Children: Another vulnerable group requiring social care is children. The physical and mental health of a child is closely related to the physical and mental health of the caregiver and surrounding environment. Therefore, a healthy environment at home and around helps a newborn grow into a healthy child. On the contrary, an unhealthy environment at home and around negatively affects the overall growth and development of a newborn into a healthy child. Also, children are more vulnerable than adults to environmental risks such as unhygienic living condition, lack of safe drinking water, etc. Unlike adults, they have little or no control over their environment, may be unaware of the environmental risks and unable to make choices to protect their health and well-being (WHO 2017b). In 2015, 26% death of 5.9 million children below the age of 5 years could have been prevented by addressing the

environmental risks (WHO 2017b). Further, children are also vulnerable to homelessness, economic difficulties, problems with substance abuse, abusive home environment, disabilities and illness, etc., which decrease their quality of lives. Therefore, to promote the overall welfare and improve the quality of life of vulnerable children, a wide range of social care services are needed either within their own home environment or in other care facilities funded by public or private agencies. Some examples of such services to safeguard and promote the welfare of vulnerable children are assessment and care planning for children at risk of significant harm, provision for safe housing, protection from abusive behavior (both physical and mental), fostering and adoption services, and services for children with severe disabilities and significant illness, etc.

Families and Care Givers: Historically, women – wives, daughters, and daughters-in-law – have always been the informal care givers to children, older adults, and other individuals in family who need special care and assistance. However, changes in the family structure and promotion of gender equalities have necessitated additional social care for families and care givers. For example, most of today's families are nuclear or single family in structure, meaning that there is less number of helping hands than found in a conjugated or joined family. Further, due to the promotion of gender equality, majority of today's women have entered the work force, requiring them to play multiple roles because of which they have less time to provide additional care and support required by some members of their family (Cantor 1989). In addition, single-parent families are increasing with projected labor shortage in the twenty-first century. This situation implies that there is an increased need for surrogate care givers in such families in order to reduce the caregiver's stress.

In the context of the aforementioned needs, research has shown that social and health care need to be integrated and personalized to achieve its desired outcome (Amelung et al. 2014; Malbon et al. 2019). The following sections briefly present the integration and personalization of social care.

Integration

Sir Norman Peter Lamb, former MP of the United Kingdom, once said that people do not want health care or social care; they just want the best care. To provide the best care, social care needs to be integrated with health care because no single part of the system can deliver effectively in isolation. For example, lack of social care in times of poverty, illness, abuse, and homelessness is closely associated with illness and poor health outcomes. Poor health outcomes may intensify disability, increase immobility, and create isolation, leading to depression. Depression can cause serious harm including suicide and other self-harm such as substance abuse, etc. Therefore, integration of social care into health care is crucial because social and health care needs are interrelated and one need may affect the other. Successful integration of social care into health care requires coordination of care provided by a multidisciplinary and well-functioning team, who has different skills and work collaboratively to provide optimal care and achieve a common goal. In integrated care, client and family remain as the centerpiece whose needs are met collaboratively. The other members of the team with specialized expertise include social workers, physicians, counselors and nurses, among others. Social worker is one of the key members of the team who assesses the needs and addresses the practical, social, and emotional issues that affect the health and well-being of the client and family,

manages risk, supports independence, and coordinates care to keep people at home in collaboration with the other members of the team. Figure 1 illustrates the multidisciplinary model of integrated social care. Thus, the ability of the care team and various funding agencies to work together is the key to the success of integration (Amelung et al. 2014). Further, proper coordination of funds from the public, private, or both, along with the client's own funds and assets, is necessary to meet the cost of the care. Regardless of differences in policies, funding, infrastructure, and provision, many developed countries have adopted the whole system approaches to integrated care. Canada and the USA have successfully implemented the whole system approaches to integrated care model to serve the elderly and others in need. Some popular integrated care model in the North.

America are Program of All Inclusive Care for the Elderly (PACE) and Social Health Maintenance Organizations (Social HMOs) in the USA, *Système de soins Intégrés pour Personnes Âgées* (SIPA), Program of Research to Integrate Services for the Maintenance of Autonomy (PRISMA) and Comprehensive Home Option of Integrated Care for the Elderly (CHOICE) in Canada. The success of PACE, Social HMOs, SIPA, PRISMA, and CHOICE demonstrates important information about what works and under what circumstances in whole system approach to integrated care services (Kodner 2009). These North American examples of integrated care model suggest that the process of sustainable integration requires collective efforts of the care team and different agencies involved, so that the whole system approach to working with people, their families, and communities makes the best use of available public resources and people's own strengths and assets to bring the desirable outcome.

Social Care, Fig. 1 Multidisciplinary model of integrated social care. (Source: The author)

Personalization

Personalization is the process of making something suitable for the needs of a particular person. Therefore, personalization of social care means giving people more choices and control over

their lives in all settings of social care, whether they are provided by the formal agencies, or funded by themselves. It also recognizes the user as a person with strengths and preferences and it starts with the user instead of the service (SCIE 2012). In other words, outcomes of the personalized care must be relevant to the client and their caregivers even though they may be different from the policies and practices of the organizations. It is generally recognized that personalization of social care brings its desirable outcome. However, issues such as inequality in exercising choice and control while providing personalized care may exist. For example, fear for growing social and health inequalities has been reported in the Australian National Disability Insurance Scheme (NDIS) – a social care scheme based on an international trend toward personalization of social care. Thus, personalization of social care is a complex process and requires attention when designing policy delivery system for personalized schemes to preserve social and health equity (Malbon et al. 2019).

Summary

Need for social care will continue to rise with the rise in elderly population and vulnerable groups in the communities. Decrease in family capacity to care for the needy ones at home arising from changes in the family structure (single-family) and women entering the work force have necessitated new response from the social care, which is also integrated into health care. It is expected that in the coming years, all countries will either need to build a broad-based and integrated social care systems, or reform the existing ones making it broad-based and integrated to meet the diverse and increased need of people, families, and communities.

Definition

The identification of a “Social case” represents one of the main strategies used by policy makers, NGOs, and organizations to favor the development of socially responsible practices. During the last years, many organizations have been considered as best practices due to their attempts to integrate within their traditional practices ethical and sustainable principles. In particular, several authors started to discuss about the need to rethink global economy through the adoption of new paradigms based on social cases’ previous experience. Furthermore, the topic regards also NGOs and Governments, which represents some of the main sustainable development’s enablers identified by academics. In fact, several studies underlined the pivotal role covered by these institutions within the decision-making process related to the implementation of new forms of regulations about CSR.

The Need of Social Cases of CSR

During the last years, the international markets have been interested by several changes that have revised the traditional paradigms. This evidence was driven by several factors such as the rise of new form of nonfinancial regulations, the external pressures made by stakeholders, and the organizations’ need to maintain, gain, and repair their competitive advantage (Deegan 2019; Lozano 2015). In

this sense, contrary to the past, the current scenario is characterized by a wide number of organizations, which based their business models on sustainable and ethical principles (Geissdoerfer et al. 2017; Saxton et al. 2020). Furthermore, the disclosure of nonfinancial information does not represent a rare phenomenon due to the proliferation of reports at the international level (Dumay et al. 2015).

However, the implementation of sustainable and ethical practices by organizations requires a high degree of orientation toward these practices due to the existence of several barriers. In particular, a transition from linear to sustainable paradigms requires specific skills that mitigate the cultural, technical, and economic barriers that usually characterize these practices (Hahn and Kühnen 2013). In this sense, socially responsible strategies require an ex ante evaluation of the organizations due to the need to align corporate communication and behaviors (Schoeneborn et al. 2020).

According to this evidence, social cases’ benchmarking represents one of the main strategies used by organizations to develop their strategies. A clear example of this phenomenon is represented by the isomorphism that has characterized the quality of the nonfinancial reports prepared by the European PIEs after the transposition of the Directive 2014/95/EU. Furthermore, another example is represented by the positive correlation related to the M&A of a nonsocially responsible organizations by a Group with prior experience in CSR. In addition, a growing number of institutions started to assign awards in order to certify the sustainable behaviors of certain organizations. Finally, the financial markets reward organizations through an increase of the market value in the presence of CSR’s strategies.

However, the identification of a social case represents a complex activity due to the risks of unethical behaviors such as greenwashing, impression management, and SDG-washing (OECD 2017; Pizzi et al. 2021). In this sense, an in-depth analysis of the social case cannot exclude these risks as evidenced by the large number of

corporate scandals that have interested leading firms during the last years (Diouf and Boiral 2017; Siano et al. 2017).

Conclusion

The recent past was characterized by the rapid growth of socially responsible organizations. This paradigm shift favors the achievement of more sustainable ecosystems. However, despite the positive externalities related to the trend, the road ahead a more sustainable Planet requires further initiatives in order to engage with nonsocially oriented organizations. According to this evidence, early adopters will sustain these processes through their activities. In fact, as evidenced by some of the main policies developed by European Member States, socially responsible organizations could cover a pivotal role through their activities. In this sense, the contribution of academics will be relevant in order to share the lesson learned from the social cases within the international context.

Social Contract

Definition

Social contract is a political philosophy and theory of how governments justify the existence of the state and the exercise of government power. It is based on an imaginary state in which humans living in nature decide to organize themselves in a manner which would be recognized as the modern state – i.e., surrendering to a non-clan-based authority or to an authority imposed by violent conquest. Social contract theory further assumes that there are “natural rights,” rights which are an inherent part of human nature, which can be traded and surrendered. In its simplest form, a social contract is an agreement between people to surrender these natural rights by way of agreement to create a government that would improve their well-being by limiting violent conflict for access to and control over resources.

As a theory arising in the seventeenth century, the era of the Enlightenment, Europeans were setting the philosophical foundations for challenging monarchies, encountering peoples in other parts of the world as never and before, and there was a growing dissatisfaction with prior explanations and justifications for the status quo, particularly with religious and sanguinal explanations for the organization of governance. Social contract was an approach that provided a procedure and rationale for the organization of government, with an ultimate goal to demonstrate that social rules can be generated by rational agreement. Three well-known approaches, those of

Hobbes, Locke, and Rousseau, have provided the groundwork for subsequent refinement.

Introduction

Although the idea gained widespread interest and acceptance in the seventeenth century, it finds its roots in the ideas of classical antiquity. In Plato’s *Republic*, this agreement is described as “justice.” It is described as what transpires when parties have both inflicted and suffered injustice and come to an agreed resolution. As put in the dialogue: “[people] think that they had better agree among themselves to have neither; hence there arise laws and mutual covenants; and that which is ordained by law is termed by them lawful and just” (Book II, trans Jowett). Although Plato’s dialogue concerns the origins and nature of justice, the core idea of the social contract is evident.

Social Contract of the Enlightenment

In the era of the Enlightenment, the social contract theorists began with an idea about people in a state of nature (Sheehy 2004). The question they aimed to answer was how could people coexist in a world in the absence of a governing authority. Or, put in the positive, how was it that people came to organize themselves into a non clan-based society? There are three main Enlightenment era philosophers whose ideas came to be foundations for the debate, thinking, and actions which were to follow. These thinkers differed in their models of human nature, the nature of the grant of rights and the role expected of government.

Thomas Hobbes (1588–1679), writing in the period of the English Civil War (1642–1651), took as his model of human nature a more pessimistic model. He argued that since people are fundamentally selfish, they will struggle violently to take care of their own needs and interests without regard to others. In Hobbes words, life would be “war of all against all,” something he witnessed

in the violence around him. As a result, in his famous summary, Hobbes stated that human life would be “solitary, poor, nasty, brutish and short” (Leviathan, i. xiii. 9).

Hobbes believed that no single person in this natural state was sufficiently strong to be free of fear of others and further that no person was so weak as not to pose a threat. His solution, therefore, was that people renounce some rights in order to create a state, a “commonwealth,” that would be sufficiently powerful to protect the rights of every person. Hobbes called that governance institution “Leviathan” (Dietz 1990). In this context, Hobbes argued that citizens granted absolute and nonrescindable rights to an absolute sovereign.

The second major social contract thinker, John Locke (1632–1704), in contrast to Hobbes, took a different starting point for his argument. In Locke’s view, the state of nature, although pre-political, was not premoral. The law of nature, which Locke argued, was in his view the foundation of all morality, the invention of the deity, and bestowed upon humanity. In the state of nature, he believed, people were free to pursue their own interests and execute their plans, without interference. Locke argued that by virtue of the law of nature people were able to live in a relatively peaceful society (Yolton 1958).

In Locke’s view, people in their natural state would be morally bound by the laws of nature not to harm another in terms of life or property. In his words: “all be equal and independent, no one ought to harm another in his life, health, liberty or possessions” (Locke 1690 Second Treatise, Ch2:8). Locke realized, however, that people would not be protected by simply possessing rights. Without a government protecting the populace at large, some people who would try to harm or enslave others, and the general populace would live in fear. Following this logic, Locke argued that people would agree to form a state only if it would provide a “neutral judge” acting to protect the life, liberty, and property of those who lived in it (Gaba 2007).

A fundamental element of Locke’s social contract rested on his initial position that the government was a fiduciary which bore duties while

citizens held the rights. This thinking led to the conclusion that if a group of people disagreed with important decisions of the government of the day, the group retained the right to form a new social contract and create a new government (Gardner 1990).

A core part of Locke’s theory, however, addressed state rights, in particular, monopoly on violence and a right to taxation. To Locke the monopoly right to violence provided government with the legal means to control a society, as well as power to administer laws and to provide security. Thus the state, with the exception of self-defense, held a monopoly on violence. Further, although Locke’s social contract explicitly protected property, it did not do so in an absolute manner. Rather, property was subject to taxation.

The third major social contract theorist, Jean-Jacque Rousseau, had two distinct theories of social contract. The first, found in his essay, *Discourse on the Origin and Foundations of Inequality Among Men (Discourse)*, is an account of the moral and political evolution of humans over time. It contains a naturalist, psycho-evolutionary account of the social contract, an evolution which he sees as problematic. Rousseau believed that the state of nature was state of peace and simplicity. People lived an uncomplicated, if somewhat lonely, life. The few needs they had were easily satisfied by nature. Due to nature’s abundance and the small size of the population, there was no need to compete, and people rarely encountered one another and certainly had less cause for conflict or fear. Rousseau believed that people in the state of nature were morally pure, were endowed with empathy and pity, and not inclined to harm one another (Rousseau 2012). His view was that society corrupts humanity’s innate, natural goodness.

Rousseau’s second account, found in his treatise the *The Social Contract*, provides an ideal account. Following his prior evolutionary ideas, Rousseau recognized that the population would become denser and put people into close contact. The result would be a Hobbesian war of all against all. In that situation, the poor would consent to exploitative conditions to avoid violence. In *The*

Social Contract Rousseau argued that rather than surrendering to these relations, an alternative was following something he referred to as the general will. This general will would arise either as an expression of democratic processes or some type of metaphysical form apart from the individual desires.

The social contract is referred to as a “contract” not because of its legal character, but because it involves an exchange of promises as an agreement. The “contract” involves citizens giving up some personal power and freedom to the state and in exchange the state provides security and protections of other liberties. As a political theory, social contract theorists insist that government legitimacy is founded on a social contract. Without such a grant, governments lack legitimacy: The original populace are the source of legitimacy. Locke called it popular sovereignty (Gardner 1990).

Not social contract theorists share these views. Some libertarian philosophers hold that a social contract is real agreement between citizens and governments, and as a result they believe that the foundations of government are of questionable legitimacy. These libertarian critics suggest that each individual citizen ought to be able to decide on an individual basis, and that those who are not given the choice are there against their will – enduring a type of coercion or enslavement (Stone 2014). As a function of some of their theories of consent, they may be sceptical of democracy and oppose social contract theories generally as the social contract theories provide little opportunity for individual acts of choice.

Modern Social Contract Theory

The goal of the social contract theory is to show that members of a society have reason to support and abide by the basic social rules, laws, institutions, and/or principles of that society (Sheehy 2004). Contemporary theory of social contract was established in the sixteenth to seventeenth centuries. According to theorists such as Hobbes, Locke, and Rousseau, a social contract forms the

foundation for a non-clan- or non-ethnic-based society. It provides for institutions of governance and in most instances ensures some form of the rule of law. The original theorists of the social contract represented the initial state of nature – a state in which no government existed – and from that initial position hypothesized and formulated an ideal or preferred form of social organization or government (Sheehy 2004).

Recent Developments in Social Contract and Related Theories

In 1972, the publication of John Rawls’ notable *Theory of Justice* brought moral thinking, social contract, and political philosophy back to the main stream. Rawls argued that social contract is hypothetical, not a historical contract. The preliminary situation or “original position” is one in which all the parties to the negotiation are behind a “veil of ignorance.” This veil of ignorance, argued Rawls, operates such that each person participating in negotiating the social contract comes to the negotiation without knowing what rights and status he/she will have in the ensuing society. Accordingly, the veil of ignorance ensures that people coming from their particular contexts and environments, while capable of a sense of justice, would not develop and advocate principles of justice which would advance their own particular position or special interests (Sterba 1989). By having negotiators blind to their status, Rawls thought negotiators would negotiate for a system which was just and fair for all.

Accordingly, Rawls believed that free and rational people would agree to a social contract only if in their original position they were of equal status and capacity. They would be able to agree on a social contract only if they did not know their social status or class position, their natural traits or acquired abilities, nor their particular goals. Rawls further argued that the agreement would occur only if the particular characteristics of their own society are also hidden.

In this situation, argued Rawls, people in their original position would choose two principles of justice. The first principle requires equality

between people with respect to basic liberties, whereby each person's most extensive basic liberty should be compatible with a similar liberty for others. When these liberties cannot be exercised in all social positions, people in the initial position would favor the second principle of justice. According to this second principle, social and economic inequalities can be just only if unequal distribution of these benefits is to the advantage of the least favored members of society (Rawls 1999). Since no person knows anything about themselves and could end up being anyone else in any other status, each has concern for all and thus commitment to justice as fairness to all.

Further thinking by Thomas Scanlon, developing a view known as "Contractualism," although superficially similar to social contract thinking, focuses on policy justifications. Contractualism is distinguished from "Contractarianism," which in Hobbesian fashion argues that rational maximization of self-interests leads to the construction of moral and political authority. In contrast, Scanlon's contractualism excludes self-interest and focuses on the justification of own interests to others, as morally motivated commitment of rational people. Scanlon argued that policies can be just only where one person can require another to suffer some harm and the harmed party cannot reasonably object. This approach is different from Rawls which seeks consensus on principles. Individuals' acceptance of a principle thus depends on their own assessment of the strength of their reasons for rejecting it, compared to the alternative solutions to the issue. The reasons, Scanlon argued, allow for justifications which are responsive to the situation of others and therefore individuals are motivated not only by self-regard but also by respect for others (Wallace 2002).

Summary

The social contract theories of Hobbes, Locke, and Rousseau held that justification of the state depended on demonstrating that the people consent or accept the organization of governance

institutions. Based on that agreement, the social contract is an argument for political organization based on justice and commitment.

Modern thinkers further developed these ideas focusing on the notions of justice and the justification to solve the problem of determining what principles can be acceptable to all reasonable citizens in agreeing to social contract. Contractualist arguments see this agreement as the outcome of what suitably morally motivated people would rationally agree to as their collective morality. Whatever the motivation, rationality remains the basis for adopting a social arrangement, from early to modern social contract thinkers.

Description

The term “social dumping” refers to a multi-dimensional scenario in which labor-related criteria in one nation are lower than they should be, giving certain business enterprises an edge over their rivals. In a nutshell, it is a manner of flouting social and/or labor legislation while obtaining an “unfair” market advantage by employing low-cost skilled labor.

Introduction

“In every improved and civilized society, this is the state into which the laboring poor, that is, the great body of the people, must necessarily fall unless the government takes some pains to prevent it,” Adam Smith says in his treatise *The Wealth of Nations* (Guendelsberger, 2019). Dumping in international trade is an example of

unfair competition since products are sold at a price that does not accurately reflect their cost (European Parliament, 2018). It is viewed as unethical commercial practice because dumped goods and services pose a significant social, political, legal, and economic danger to business organizations, employees, unions, and other stakeholders. That is why Alber and Standing (2000) wrote that social dumping has a pejorative ring around it.

Even though there is much debate about social dumping, a crucial topic in the European Union, no formal definition has yet been established. “Although there is no definition in EU legislation, social dumping is a phrase used to refer to unfair competition caused by the employ of varied wage and social safety standards to various categories of employees,” Thyssen explained when addressing the European Parliament in 2015 (Eurofound, 2016). Bernaciak (2014) defined social dumping as “the practice, undertaken by self-interested market participants, of undermining or evading existing social regulations to gain competitive advantage.” It can also be explained as a situation when social standards do not advance at a pace proportional to economic growth due to external competitive pressures. The term labor-induced value drain refers to a situation in which businesses that operate in countries with lax labor standards produce and export goods at meager prices by employing unfairly inexpensive labor in relatively poor working conditions (Corden & Vousden, 2001). It is defined by Sapir (2015) as “downward social pressure as a result of competition from nations with lower social conditions.” For example, it is a case of a Croatian construction firm constructing residences in Germany and utilizing Croatian staff who are EU citizens with employment contracts in Croatia and are temporarily stationed there. It is a fair presumption that Croatian workers would not have the same wages as their German counterparts, giving a comparative advantage to the company that employs them.

Vaughan-Whitehead (2003) claims that social dumping shares a common goal with trade dumping, in that both are used to gain a higher market share by offering lower prices. She defines social

dumping as “any practice pursued by an enterprise that deliberately violates or circumvents legislation in the social field or takes advantage of differentials in practice and/or legislation in the social field in order to gain an economic advantage, notably in terms of competitiveness, the state also playing a determinant role in this process.” However, she argues that the social implications of social dumping can be more harmful than trade dumping, as it often involves exploiting vulnerable workers and creating dangerous working conditions. Despite the negative impacts of social dumping, many businesses continue to engage in this practice to gain a competitive advantage in the marketplace. Center for Economic Policy Research defines it as a management decision in a developed country to supply its domestic market through production based in a developing or low-wage country where labor standards do not comply with minimum legal requirements adopted by the home country, therefore allowing the business to enjoy lower costs (Eurofound, 2016).

Social dumping can therefore result from (customized and replenished Sapir, 2015):

- Imports of cheaper goods from developing or low-wage countries to developed or high-wage countries.
- Imports of services employing posted workers from developing countries. Posted employees are people with a work contract in a developing country who are temporarily transferred to a developed nation by their employer while performing a specific project/contract.
- Relocation of business activities from developed to developing countries (typically production, but it can also be R&D, accounting, or any other phase in the value building chain).
- Thwarting the exploitation of a shadow economy and hidden work that mocks official policies and programs by relying on unreliable numbers and statistics.

Social Dumping and EU Perspective

Social dumping is a complex and divisive issue in Europe, with the term often carrying negative

connotations that imply unfair treatment of workers (Eurofound, 2016). Despite this, social dumping practices can also be found within domestic markets and are opposed by groups like the European Trade Union Confederation. Meanwhile, business organizations view social dumping as a beneficial strategy for their members' success. Given the complex and sensitive nature of this topic, there is much more to be said on the matter in the near future.

The issue of social dumping has generated a lot of debate. “In our union, the same work at the same place should be remunerated in the same manner,” stated former European Commission president Juncker in 2014, addressing both desired context and varied approaches among newer and older EU member states. In political speeches, anti-EU politicians frequently make use of social dumping to gain support and legitimacy.

In 1993, the EU's “global competitiveness” strategy was drawn up, and the single European market was established. In the 1990s, the tenets of the four freedoms (freedom of labor, capital, commodities, and services) were given fervent priority; the freedom of labor is obviously of particular interest here. European Union's citizenship resulted from the Maastricht treaty; it gave all EU nationals freedom to live, move, and work freely in all member countries (Sandberg & Nielsen, 2014 cites Vestergaard & Sørensen, 2004).

Social dumping is regarded as a by-product of open borders and the free movement of labor. Western Europeans are concerned about the detrimental influence social dumping has on their welfare systems, which is why there is an unfavorable attitude toward immigration in some nations. Eastern European countries have lower minimum wages, making them an attractive place for foreign direct investment and for gaining a competitive advantage through the hiring of cheap skilled labor. According to Bernaciak (2014), the accession of “post-communist Europe” into the European Union in 2004 has enabled firms to relocate production to cheaper or less regulated areas in Southern and, more recently, Central-Eastern Europe, or utilize the threat of exit to extract concessions from employees in more stringent regulatory settings. How it influenced the flows and transfers of money and profits showed

Social Dumping (CSR), Fig. 1 Inflows and outflows in Eastern Europe 2010–2016. (Capital and ideology. Cambridge and London: The Belknap Press of Harvard University Press)

Piketty (2020) in Fig. 1. Picketty explained that, on average, the annual net flow from the EU to Poland was 2.7% of GDP each year between 2010 and 2016 (the difference between total spending received and total contributions paid to the EU budget). Over the same period, profits and other property income (net of the corresponding inflow) outflow was 4.7% of GDP. For Hungary, these percentages were 4.0% and 7.2%.

Labor migration from new, developing EU member countries has recently become a major issue. Several Central European EU member state ministers have called for better application of current rules, while those from developed EU nations are demanding the toughening of measures to guarantee “equal pay for equal work at the same place.” After the accession of new member states to the EU in Southern and Eastern Europe, many “old” member states temporarily imposed labor market restrictions. However, these restrictions have had the unintended consequence of encouraging fraudulent self-employment among migrants that may amount to social dumping. Migrants have traditionally been paid lower wages than local workers in receiving nations, allowing businesses to save on

employee compensation and social contributions. Furthermore, the availability of foreign workers has decreased companies’ reliance on local workers, putting pressure on wages and working conditions in host countries.

As a result, everyone is perplexed. Employees in exporting nations are not being compensated fairly for the value they deliver and the profits their firms make. If the government was compelled to give special treatment to employers who receive cheaper concessions or exemptions from regulation, budgets in exporting countries would be lost. Employees in importing countries are also perplexed. They suffer from low foreign competition due to production being relocated to cheaper international locations.

Companies that benefit from social dumping are those that operate in a foreign country and gain inexpensive skilled labor, which results in increased profits. Customers of such firms also benefit since they obtain cheaper goods, which is why this kind of production and consumption is usually well accepted by local customers who rarely question the source of cheap items, as long as they are accessible. This is partially why certain writers feel that market actors’ social

dumping techniques are encouraged by liberalization and deregulation policies (Alber & Standing, 2000; Peters, 2008; Boulhol, 2009; Bernaciak, 2014).

In industries where robots are still inadequate in fine motor control, speech, pattern recognition, and empathy, the most cost-effective and straightforward solution is to use low-wage human labor (Guendelsberger, 2019). The textile industry in Europe is an excellent example of a local industry suffering from social dumping. Many of it has shut down production in Europe and relocated to developing nations with inexpensive labor and abysmal social norms. Because of lengthy value chains, the environmental and social criteria required in exporting nations are unknown to the ultimate consumers who enjoy low prices. Simultaneously, textiles manufacturing has risen, accompanied by the idea of “quick fashion,” which implies fast-changing fashions that urge customers to buy more and change their clothes more frequently. The introduction of new technologies and processes has significantly accelerated the production cycle, resulting in increased textile waste, environmental problems, and the industry’s continued distancing from the circular economy. Meanwhile, the local textile sector has survived only if it has captured some unique preferences or clients with greater purchasing power that are not sensitive to price.

In recent decades, European labor markets have seen significant shifts in pay levels and employment conditions on a wide scale (Sandberg & Nielsen, 2014). The pay gap impacts all aspects of the economy, from wage levels to productivity to security to working hours, job permanency, and vacation rights. That is why European Parliament (2016) adopted a Resolution on Social Dumping in the EU. The European Parliament has recognized that there is a wide range of practices and situations that can be classified as social dumping, which can have a negative impact in terms of economics, social welfare, and public finances:

1. The economic aspect – it occurs when companies use illegal or abusive practices to gain an unfair advantage over their competitors, often leading to market distortions that harm

legitimate businesses, particularly small- and medium-sized enterprises (SMEs).

2. The social aspect – it can result in discrimination and unfair treatment of workers across the EU, depriving them of their basic rights to fair wages and social protections.
3. The financial and budgetary aspect – the non-payment of due social security contributions and taxes resulting from social dumping represents a threat to the financial sustainability of social security systems and the member states’ public finances.

To address these and related problems, it is essential that governments take strong action to prevent and combat social dumping through policies aimed at promoting equity and fairness in the workplace.

European Parliament calls for several actions to curb social dumping, such as: reinforcing controls and coordination between the EU member states; addressing regulatory gaps in enforcing the principles of equal pay and equal social protection; helping social systems to converge; combating social dumping for mobile workers in the most vulnerable industries (e.g., textile, construction, transportation, fast food, and warehousing, among others); and limiting the free circulation of posted workers (Eurofound, 2016). The Commission proposed a national minimum wage based on the principle of a gradual approach to achieving at least 60% of the national average wage, with an aim to minimize excessive wage gaps as much as possible. The report also called for a mechanism in which firms could be held liable for a higher degree of care, not only their own subsidiaries but also third-country subcontractors who worked with them, to prevent corruption, human rights abuses, significant physical harm or environmental damage, and the violation of ILO conventions.

Global Impact of Social Dumping

In a narrower sense, social dumping is defined as “respecting or failing to respect the law,” according to Vaughan-Whitehead (2003),

Social Dumping (CSR), Fig. 2 The rise of inequality around the world, 1980–2018. (Capital and ideology. Cambridge and London: The Belknap Press of Harvard University Press)

whereas in a broader sense, it refers to “unfair competition.” Social dumping is not exclusively limited to those from new EU member states or developing countries. While lower wages and social protections in other countries may incentivize rule evasion, this does not represent the whole picture. Multinational companies from high-wage countries actively search for ways to skirt regulatory constraints in both developed and developing nations. This can force other market participants into social dumping practices. For example, large construction companies may set low prices for subcontractors, in order to keep their own costs down while absolving themselves of responsibility for rule violations. Consequently, this puts pressure on lower-level firms (often populated by workers from developing countries) to engage in social dumping (Bernaciak, 2014). The result of social dumping is rising inequalities worldwide, as shown in Fig. 2. Piketty (2020) explains how the top decile share (the 10% highest incomes) in total national income grew from 26% and 34% in 1980 in the different parts of the world to 34% and 56% in 2018. Inequality increased everywhere, but the size of the increase varies significantly

from country to country at all levels of development. For example, it was more significant in the USA than in Europe and greater in India than in China.

The inequality of different regions is shown in Fig. 3. Piketty (2020) states that in 2018, the share of the top decile (the 10% highest incomes) in national income was 34% in Europe (EU+), 41% in China, 46% in Russia, 48% in the USA, 54% in sub-Saharan Africa, 55% in India, 56% in Brazil, and 64% in the Middle East.

United Nation’s Guiding Principles for Business and Human Rights (UNGPR)

Social dumping between developed and developing worlds created a significant increase in inequality and a decrease in the level of fair working conditions. The exploration of vulnerable countries and weak social protection is extensively used by many multinational companies that benefit from long value chains. The United Nations 2011 launched United Nations Guiding Principles for Business and Human Rights

Social Dumping (CSR), Fig. 3 Inequality in different regions of the world in 2018. (Source: Capital and ideology. Cambridge and London: The Belknap Press of Harvard University Press)

(UNGP) to address this issue. These principles aim to answer who is responsible for employee human rights in exporting third-world nations. The UNGP recognizes the responsibility of governments to protect human rights and promotes the “Protect, Respect, and Remedy Framework.” The UNGP emphasizes ensuring that domestic laws are adequately enforced, noting that failure to do so is frequently a significant legal gap in state practice. Such laws might range from non-discrimination and labor laws to environmental, property, privacy, and anti-bribery laws. States should advise on appropriate methods, including human rights due diligence, and how to consider issues of gender effectively, vulnerability, and/or marginalization, recognizing the specific challenges that may be faced by indigenous peoples, women, national or ethnic minorities, religious and linguistic minorities, children, persons with disabilities, and migrant workers and their families. Business organizations have to respect human rights, which entails complying with internationally accepted human rights – those defined at the least in the International Bill of Human Rights and the principles guaranteeing

fundamental rights set out in the International Labor Organization’s Declaration on Fundamental Principles and Rights at Work. Human rights problems may impact business enterprises through their actions or owing to their commercial ties with other stakeholders (United Nations, 2011a).

The International Labor Organization’s Declaration on Fundamental Principles and Rights at Work, which all of its member nations are required to follow, includes four categories of principles and rights: freedom of association and the right to collective bargaining; the elimination of compulsory labor; the abolition of child labor; and the elimination of discrimination in respect of employment and occupation. These are covered by the eight core conventions of the International Labor Organization (ILO).

At the same time, national laws may not comprehensively cover all internationally recognized human rights. They can be feeble, they might not apply to everyone, and governments or the courts may not enforce them. UNGP clarifies that companies should respect the higher standard where national laws fall below internationally

recognized human rights standards. Where national laws conflict with those standards, companies should still seek ways to honor those standards' principles within the bounds of national law. Enterprises can affect the human rights of their employees and contract workers, their customers, workers in their supply chains, communities around their operations, and end users of their products or services (United Nations, 2011b).

UNGP has emerged as a more effective instrument for promoting human rights in the value chain for multinational and exporting firms from developed countries. It has quickly become one of the most vital tools for socially responsible actions and practices.

The European Commission initially backed member states in adopting action plans on UNGP as a voluntary option. Since the implementation of UNGP has not improved, the European Commission has announced its intention to implement a new EU-wide "mandatory supply chain due diligence" regime based on and compatible with the UNGP. The new legislation is expected sometime in 2023.

Corporate Social Responsibility (CSR) as a Strategic Tool to Combat Social Dumping

The United Nations World Summit Outcome Document (2005) has identified economic development, social development, and environmental protection as three critical pillars of development. We should look at them from a more comprehensive and holistic standpoint since each dimension is interrelated and supports the other two. The social category is further divided into the following subcategories: labor, society, human rights, and product responsibility (Perez-Batres et al., 2012).

Responsibility for the value chain and working conditions applied in exporting countries suggested by UNGP have aimed at erasing social dumping. Because most of the social dumping takes place in the value chain, many other regulations and laws encourage European businesses to be more concerned with working and human

rights conditions in their value chains. Directive on nonfinancial reporting (2014/95/EU) and a draft of the newly developed directive on corporate sustainability reporting emphasize responsibility for the company's value chain. Many reporting standards, such as the example Global Reporting Initiative's Reporting Standards (GRI Standards), are similar. The emphasis on responsibility for the value chain is because most businesses in Europe have neglected to include employee social and working conditions in their supply or value chains in their CSR efforts. Most of the CSR's focus has been on the conditions inside the company's operating locations and in the communities where reputation is linked to corporate success. Many firms have started incorporating supply chains into their CSR efforts in recent months due to UNGP and the laws and standards referenced above. The shortening of value chains that happened because of Covid-19 and the greater concentration of companies to local production and local suppliers made it easier to control the supply chain and could eventually help decrease social dumping practices.

Summary

The complex and ambiguous nature of the social, political, and economic climate in Europe, which lacks shared legislative references and commercial methods across the EU, makes social dumping a perplexing and challenging problem to be investigated and improved. Even though more stringent regulation is to be expected, as it may improve the status of social dumping, it is not likely that the problem will be completely solved in the near future. The global impact may worsen in the years to come due to the disruption of global value chains due to climate change, Covid-19 pandemic, and volatile energy markets.

Social business; Social business venture; Social economy enterprise; Social entrepreneurial venture; Social entrepreneurship organization

Definition

Social enterprise is a common term describing the activity of various organizations, projects, and ventures that pursue a social mission by using market mechanisms (Chell 2007; Haugh 2006; Mair 2010; Okano 2019). The reason for its existence is to solve or reduce and mitigate social problems, meet social needs, and initiate social change (Austin et al. 2006). At the same time, a social enterprise is characterized by market orientation, innovation, proactivity, risk-taking, and bottom-up, autonomous status (Lumpkin et al. 2013; Sullivan Mort et al. 2003). This type of organization is oriented

toward creating a mixed value consisting of economic, social, and environmental value – known as multiple bottom lines, triple bottom line, or double bottom line (Bibby 2002; Emerson 2003; Thompson and Doherty 2006) (see ► [“Triple Bottom Line”](#)).

Social enterprises take different legal forms depending on historical, socioeconomic, cultural, and other national contexts (Chandra and Kerlin 2021; Defourny and Nyssens 2010, 2021; Kerlin 2012, 2017). They operate as associations, foundations, cooperatives, social cooperatives, mutual societies, or nonprofit companies, as well as obtain social enterprise status (Borzaga et al. 2020).

A social enterprise is referred as a hybrid organization (see ► [“Hybrid Organizations”](#)) because it combines in its activities different objectives, resources, motivations, products manufactured, ownership, and others (Battilana et al. 2012; Doherty et al. 2014; Evers 2005; Grassl 2012).

Conceptual Foundation

The term “social enterprise” appeared first in public discourse in the 1980s (Defourny and Nyssens 2008, 2010). It is analyzed in relation to the concept of social entrepreneurship (Bacq and Janssen 2011; Chell 2007; Dacin et al. 2010; Hota et al. 2020; Mair and Marti 2006) (see ► [“Social Entrepreneurship”](#)) and in reference to social economy (Borzaga et al. 2020; Defourny and Nyssens 2008, 2010, 2021; Orhei 2011). The emergence and activity of social enterprises are a global phenomenon (Bosma et al. 2016; Lepoutre et al. 2013).

The increased interest in the solutions offered by social entrepreneurship is explained by the social, economic, and political changes in the last decades of the twentieth century and, in general, by the growth of social problems and social inequalities requiring innovative ways to solve them (Yunus 2007). The origins of social entrepreneurship are identified in business ethics (► [“Corporate Social Responsibility”](#)) and the growing interest of the commercial sector in

socially responsible activities and in the need to strengthen the independence and effectiveness of nonprofit organizations (García-Jurado et al. 2021).

Academic discourse distinguishes three perspectives in defining social enterprises (Comini et al. 2012): the European, the American, and the emerging (developing) countries. In the European context, social enterprise is described as a private activity conducted in the public interest, characterized by participatory governance, democratic control, and social ownership (Defourny and Nyssens 2008; Laville et al. 2015; OECD 1999; Pestoff and Hulgård 2015). In the USA, two independent schools describing social entrepreneurship stand out: the social enterprise school of thought (also called the earned income school of thought), which emphasizes the use of market resources and managerial practices to increase the efficiency and effectiveness of the social sector (Dart 2004; Eikenberry and Kluver 2004), and the social innovation school of thought, which focuses on the social entrepreneur and the innovations introduced to meet social needs (Defourny and Nyssens 2010; Hoogendoorn et al. 2010). The socially inclusive business in developing countries (South America, Asia) is focused on poverty reduction, aiming at scale, sustainability, and effectiveness of enterprises and their long-term impact.

The context for the operation of social enterprises is determined not only by the space (geographical area) of their operation but also by time, tradition, human life cycle, gender, religiosity or spirituality, stakeholders, field of work, sphere of action, and the disciplinary origin represented by the researcher (Chanda and Kerlin 2021). Thus, the multidimensionality and multifaceted nature of social enterprises is indicated (Chell et al. 2010).

Issues

Considering the importance of social enterprises in the economy, society, and state, there is a need for research in this area. This topic is of interest to public institutions (OECD 1999, 2003; European

Commission 2014) and the research community (Granados et al. 2011; Hota et al. 2020; Majumdar and Reji 2020; Romani-Dias et al. 2018; Short et al. 2009).

The interests of social entrepreneurship researchers focus on four areas: defining social enterprises and related concepts, comparing social enterprises with other organizational forms, analyzing the entrepreneurial process, and analyzing the determinant for the development of social entrepreneurship (Urbano et al. 2017). At the same time, the essence of the phenomenon, the social aspects of social businesses, innovation, human resource management, business strategies and value creation, and challenges faced by social entrepreneurs are of interest to researchers (Gupta et al. 2020).

In other words, the unit of observation within social enterprises can be mission-services relationship, legal form, business model, innovation, and governance (Hoogendoorn et al. 2010), but the knowledge of shared value creation and social impact measurement is of particular importance today (European Commission & OECD 2016; Grieco et al. 2015; Ormiston and Seymour 2011). The activities of social enterprises are evaluated not only in terms of generating social benefits but more broadly in terms of assessing their ability to create shared value (Porter and Kramer 2011).

Future Directions

Social enterprises are an element of socio-economic practice that has been developing in different parts of the world for more than 30 years. They are the subject of research within social entrepreneurship and social economics, but these areas of knowledge have not yet achieved the status of a well-established research field (García-Jurado et al. 2021). Research in this area is a new and challenging area to explore, characterized by a number of weaknesses, such as the lack of a clearly established theory, the lack of quantitative and qualitative data, the vagueness of concepts fundamental to the area (e.g., social value), the poorly outlined context

of the analyses carried out (Saebi et al. 2019), and paradoxes arising from the very nature of enterprises combining different orders and logics of action (Peattie and Morley 2008; Nicholls 2010). The future topics worth exploring in this field are as follows (Gras et al. 2014): innovation within social enterprises, forms and business models of social enterprises to ensure their sustainable development, contextual factors' influence upon social ventures (see ► [“Social Business”](#)), shared value, and social impact. Topics such as ethical aspects of social enterprises' cooperation with stakeholders (support recipients, employees, local communities, donors, customers, etc.) are also interesting and worth exploring.

Summary

A social enterprise is any business venture created with a social purpose that operates on a continuum – socially responsible enterprises and nonprofit organizations operating for profit (Alter 2007; Perrini 2006). Social enterprise is defined as a hybrid organization (Doherty et al. 2014; Grassl 2012) and is assessed in terms of the product produced, the outcome, and the impact (Denny and Seddon 2014). Such organizations take different legal forms depending on institutional circumstances and context. Furthermore, distinctions are made between organizations closer to market logics and those that reflect the predominance of social logics. At the same time, different types of social enterprises are distinguished spatially (geographically) (Comini et al. 2012; Hoogendoorn et al. 2010) and different types of business models for social enterprises are identified (Grassl 2012).

Definition

The impacts to social and economic systems made by industrial and environmental changes have long been of interest to social scientists. Social impacts (SI) are defined by the Interorganizational Committee on Guidelines and Principles for Social Impact Assessment (1994, p. 1) as “consequences to human populations of any public or private actions that alter the ways in which people live, work, play, relate to one another, organize to meet their needs and generally cope as members of society.” Social impact assessment, as a process of analyzing, monitoring, and managing the intended and unintended social consequences, both positive and negative, is therefore strongly linked to the concept of corporate social responsibility (CSR). While CSR holds enterprises responsible for their impacts on society, the SIA should provide the tools and measures for assessing the effectiveness of CSR. In the following entry, the SIA is defined, and the social assessment process cycle and SIA methodologies are discussed.

Introduction

The impacts to social and economic systems made by industrial and environmental changes have long been of interest to social scientists. In 1969, the National Environmental Policy Act (NEPA) was published, and, since then, the environmental impact assessment has been the key component of environmental planning and decision-making (Interorganizational Committee on Guidelines and Principles for Social Impact Assessment 1994). In the early 1970s, in the social impact assessment (SIA), the first formalized set of practices and procedures was established to document and predict the socioeconomic impacts of large-scale projects (Jacquet 2014). Social and environmental assessment become more and more important, as planning agencies insisted on providing a prior assessment to identify possible adverse consequences of interventions taken by organizations. For example, the World Bank requires their grant holders to monitor and assess

the socioeconomic effects of awarded grants, according to strict criteria.

Social impact assessment is strongly linked to the concept of corporate social responsibility (CSR). According to the European Commission (2011), CSR refers to processes that “integrate social, environmental, ethical, and human rights concerns into their business operations and core strategy in close collaboration with their stakeholders with the aim of:

- maximizing the creation of shared value for their owners/shareholders and for their other stakeholders and society at large;
- identifying, preventing and mitigating their possible adverse impacts” (EU Commission 2011, p. 6).

While CSR holds enterprises responsible for their impacts on society, the SIA should provide the tools and measures for assessing the effectiveness of CSR.

Although SIA emerged as a tool for external control provided by independent agencies, it has gained the attention of social and business organizations (Dendena and Corsi 2015). Nongovernmental organizations (NGOs) are interested in monitoring their impact, as this enables them to identify the positive effects of their projects and justify the financial support they are requesting from the government. In turn, business organizations are interested primarily in measuring the impact their activities may have in terms of financial benefits. Here, both tangible and intangible aspects are carefully assessed and incorporated into an evaluation and monitoring strategy. Organizations exert a great deal of positive impact in providing jobs, offering innovative products, and improving quality of life; however, their undertakings often also have adverse impacts, such as jobs with poor or unsafe working conditions, production of dangerous products, or pollution of the environment.

After the financial crisis of 2008–2009, numerous studies investigated the causes and the costs to society at both the macro and micro levels. As Ötke-Robe and Podpiera (2013) note, “The financial crisis that hit the world economy in

2008–2009 has transformed the lives of many individuals and families, even in advanced countries, where millions of people fell, or are at risk of falling, into poverty and exclusion” (Ötke-Robe and Podpiera 2013). This example shows how influential the social impact of business might be and how important it is to consider its consequences in terms of sustainable development.

Assessment of Social Impacts

Social impacts (SI) are defined as the “consequences to human populations of any public or private actions that alter the ways in which people live, work, play, relate to one another, organize to meet their needs and generally cope as members of society. The term also includes cultural impacts involving changes to the norms, values, and beliefs that guide and rationalize their cognition of themselves and their society” (Interorganizational Committee on Guidelines and Principles for Social Impact Assessment 1994, p. 1). Social impacts may affect lifestyle, culture, community, quality of life, and health. Thus, the social impact measurement is an attempt to capture, describe, and account for the extra value a given activity creates or destroys (The SROI Network 2012). The assessment of social impact (SIA) includes “processes of analyzing, monitoring, and managing the intended and unintended social consequences, both positive and negative, of planned interventions (policies, programs, plans, projects) and any social change processes invoked by those interventions” (Vanclay 2003, p. 6). The aim of social impact assessment is, therefore, to ensure that development will maximize benefits and minimize costs. In the traditional view, economic value is generated by the business organization, and social value is the domain of the nongovernmental sector (Weisbrod 1988). Therefore, in their assessments, decision-makers in the regulatory domain or in the business sector often do not consider the difficult to measure costs and benefits of a qualitative nature. In consequence, social impacts are often ignored or not included in the valuation studies

(Maas and Liket 2011). By focusing on the impact of the whole life cycle of the project, SIA enables an extension of the single bottom-line to a two (Clark et al. 2004) or three bottom-line approach (Elkington 1999). As social, economic, and bio-physical effects are inextricably linked, any change in one of these domains will cause changes in subsequent domains. SIA should capture in a holistic way the change process as well as the consequences occurring in all included domains (Vanclay 2003).

Assessing a project according to a broad scope of impacts, such as economic, social, or environmental, helps to bring a more ecologically, socioculturally, and economically sustainable and equitable society. SIA not only helps to identify and limit adverse or unintended impacts but also focuses on proactive development of better outcomes. By gathering information from stakeholders directly or indirectly affected by the project, it is possible to consider a wide range of perspectives, expectations, and intentions. SIA is said to contribute to the process of adaptive management of policies, programs, plans, and projects. This enables working on both monitoring the effects and transformation and/or designing of the process and operation of planned interventions that lead to certain impacts (Vanclay 2003).

Social Assessment Process Cycle

The social assessment process begins with the characterization of the existing state and requires deep analysis of the project content and identifying and analyzing the stakeholders, as well as social factors and variables. Mapping of the outcomes requires implementing the theory of change, which describes the relationship among inputs, taken activities, outputs, outcomes, and impacts. Therefore, the analysis of data is used to develop mitigative plans and subsequent consultation with stakeholders. Implementation of mitigative plans, enhancing public participation, and ensuring monitoring with active stakeholder involvement close the process (Rietbergen-McCracken and Narayan 1998). Based on the

Guidelines and Principles for Social Impact Assessment provided by the Interorganizational Committee on Guidelines and Principles for Social Impact Assessment (1994) and the International Principles for Social Impact Assessment endorsed by the International Association for Impact Assessment (IAIA), the following principles specific for SIA practice may be formulated (Social Impact Assessment – definition – IAIA website; Vanclay 2003; Interorganizational Committee on Guidelines and Principles for Social Impact Assessment 1994).

1. Fundamental assumptions

SIA should identify a diverse scope of stakeholders and involve all potentially affected groups and individuals. SIA should include equity considerations; this means that clear identification of possible benefits and threats for all affected groups, including underrepresented ones, should be provided.

2. Scope and stakeholders

SIA should be focused on the assessment of issues and concerns that really count, and not refer only to those that are easily measurable. This also means that SIA should engage its stakeholders to provide valuable data and should be inclusive, respectful, meaningful, and tailored to the needs of potentially impacted stakeholder groups. SIA should also take into account differences in local cultures.

3. Advance reflection on planned interventions

Many social impacts of planned interventions can be predicted; therefore, these should be addressed to reduce their negative social consequences and enhance their positive impacts. The potential mitigative measures of social and environmental impacts should be considered in advance. Also, when impacted communities approve the planned intervention and where they are regarded as beneficiaries, SIA should consider the alternatives, especially in cases when some unavoidable impacts are expected. All these concerns should be reported to the project planners, so that actions and alternatives may be considered.

4. Methodological approach

SIA should provide a clear description of methodological approaches, identify the most suitable methods and assumptions, and define the significance of the changes in advance. SIA is to be based on objective, comprehensive, social impact analysis that requires trained social scientists who are SIA practitioners qualified to provide high-quality results. The project should rest upon the most up-to-date information. This requires identification of appropriate data sources, use of published scientific literature, and primary and secondary data from the affected area. In cases where some data is not accessible, SIA should provide a plan for gaps in data management measures.

5. Conducting SIA

SIA should be an integral part of the development process, involved in all stages from inception to final stage, including audit. Implementation of monitoring and mitigation programs will enable management to address uncertainty resulting from potential adverse impacts.

6. Ethical concerns

In all planned interventions and their assessments, avenues should be developed to build the social and human capital of local communities and to strengthen democratic processes. There should be no use of violence, harassment, intimidation, or undue force in connection with the assessment or implementation of a planned intervention. Developmental processes that infringe on the human rights of any sector of society should not be accepted.

measurement may be divided according to its prospective user:

1. Methods developed for nongovernmental or governmental corporations: social return on investment (SROI), Ongoing Assessment of Social Impacts (OASIS), social cost-benefit analysis (SCBA), and local economic multiplier (LEM)
2. Methods developed for for-profit organizations: social return assessment (SRA), Atkinson Compass Assessment for Investors (ACAFI), triple bottom line (TBL), Measuring Impact Framework (MIF), and Best Available Charitable Option (BACO)

A method initially developed for one type of organization could be adapted for use by other kinds of organizations. In general, social impact assessment methods may differ according to purpose (screening, monitoring, reporting, evaluation), time frame (prospective, ongoing, retrospective), orientation (input, output), length of time frame (short or long term), perspective (micro, mezzo, macro), and approach – process methods, impact methods, or monetization (Maas and Liket 2011). Other examples of social impact assessment methods include social cost-benefit analysis (SCBA), social impact assessment (SIA), social return on investment (SROI), and participatory impact assessment (PIA).

Scope of Application for Social Impact Assessment

Originally the most researched areas of impact assessment covered population, employment, and housing issues. Over the years, the field has greatly expanded and currently includes a wide spectrum of research, e.g., impacts to physical and psychological health and well-being and a new focus on long-term impacts related to community sustainability (Esteves et al. 2012).

In 1994, the Interorganizational Committee on Guidelines and Principles for Social Impact Assessment recommended a list of SIA variables in five general categories:

Social Impact Assessment Methodologies

Since the 1990s, many methods for measuring social impact have been developed.

Based on the literature, research, Internet searches, and expert information, Maas and Liket (2011) identified 30 quantitative (social) impact measurement methods. The

1. Population characteristics, which refer to changes in populations, ethnic and racial distribution, relocated populations, influx or outflow of temporary workers, and seasonal residents
2. Community and institutional structures metrics, which refer to voluntary associations, activities of interest groups, size and structure of local governments, historical experience with changes in employment, income characteristics, employment equity of minority groups, local/regional national linkages, industrial/commercial diversity, and presence of planning and zoning activities
3. Political and social resources characteristics, which refer to the distribution of power and authority, identification of stakeholders, interested and affected parties, and leadership capability
4. Individual and family changes metrics, which refer to perceptions of risk, health, and safety, concerns related to displacement or relocation, trust in political and social institutions, residential stability, attitudes toward policy/project, family and friendship networks, and concerns about social well-being
5. Community resources metrics, which refer to changes in community infrastructure, land use patterns, and effects on cultural, historical, and archeological resources

These variables were intended to be suggestive and provide a starting point for social assessors (Interorganizational Committee on Guidelines and Principles for Social Impact Assessment 1994). Since then, SIA has been applied to a wide range of planned interventions in the field of sustainability, including natural resources management, demographic changes, conflict management, or assessment of social impacts that derive from different types of incidents, such as disasters (Vanclay and Esteves 2011). The techniques of SIA have found broad applications in the not-for-profit sector and social enterprises (Molecke and Pinkse 2017) in projects aimed at increasing quality of life and bettering living conditions in developing countries and also in protection of human rights (Esteves et al.

2017; van der Ploeg and Vanclay 2017). SIA has gained some popularity in the healthcare sector (Banke-Thomas et al. 2015) but also – as it brings a participatory perspective and enables strengthening of the stakeholder view – may be beneficial in investigating the social impact of practices of business institutions. The literature provides also examples of SIA usage in diverse sectors, such as infrastructure projects, energy sector, and transportation (Elkington et al. 2006; Then et al. 2017).

Limitations

Despite the growing interest in SIA methodology and the wide scope of its application, there are some concerns that limit its usage. First, researchers point out the poor experience of project managers regarding social issues. The lack of competence in this field toward individuals responsible for commissioning and delivering impact assessments may hinder the assessment itself. Secondly, SIA practitioners may find it difficult to make their point while proposing and developing alternatives for agreed-upon actions. Estimating the best possible solutions often requires that political decisions be made. In this case, the particular interests of the most influential group may prevail over the interests of a less influential group. Conducting SIA against agreed-upon principles may, in turn, decrease the objectivity and credibility of the method. The lack of financial support provided by regulatory agencies may impact the quality of the conducted SIA, resulting in compliance to just the minimal standards agreed upon by the policy makers. SIA projects require high-quality data; secondary data sources become quickly outdated, and it is necessary to supplement desktop research with local data. Also, methodological issues, such as reliability and validity and robustness and significance levels, are weaknesses in many SIA studies and negatively impact the quality of the analysis. SIA also often fails in fulfilling public expectations of being a deliberative process to determine the acceptability of a project. When seen as just an incremental project

improvement or an attempt for project legitimization, SIA may be underestimated and perceived as a process of low significance (Esteves et al. 2012).

Summary

Social impact assessment is still a relatively young concept, but its importance is increasing within the changing paradigm as to how effective action is defined. The requirements of SIA are changing, and a highly adaptive approach is required to comply with the expectations of various business, governmental, and nongovernmental organizations.

SIA requires a reflective approach in evaluating both its theoretical bases and the extent to which its practice may sustain organizational development and enhance its attractiveness for diverse groups of stakeholders.

Good SIA practice points at its key features, such as its participatory character, orientation toward important matters, affected people, proponents, and regulatory and support agencies. SIA should also increase understanding of how to conduct change and how to respond to its consequences (Esteves et al. 2012; Vanclay 2003).

[Sustainable innovation](#)

Definition

The last recent decades witnessed a fundamental change in the philosophy of doing business in which the underlying motive is to create value for society rather than increasing the wealth of shareholders. This ultimate shift in business perspective spurred the emergence of the term “social innovation” (Phillips et al. 2019). Social innovation as an overarching research stream encompasses a line of intra and interorganizational efforts that primarily focus on easing societal problems. Although the definition of social innovation remains contested, the common feature of majority of the definitions reflects the innovative activities to create and realize novel solutions for societies’ unsolved problems and unmet needs such as poverty, epidemics, environmental problems, human rights, and social inequality (Mulgan 2006; Phills et al. 2008). In this domain, social innovation echoes the innovative efforts of social entrepreneurs who address the societal problems and initiate social transformation through founding profit or non-profit oriented organizations. Accordingly, social entrepreneurs are considered as the generators of social innovations that are needed for the well-being of societies rather than maximizing profit of shareholders. In other words, social innovations are deliverers of sustainable outcomes that are beneficial for societies.

Introduction

Societies worldwide are struggling with fundamental challenges. Therefore, governments are

seeking ways to resolve these problems by encouraging innovative practices which are viewed as the panacea for these severe issues (Lubberink et al. 2017a). The industrialization as the core hallmark of civilization is ignited by the capability to undertake innovations, thus, civilizations are considered as the outcomes of innovations (Simms 2006). As the initial conceptualization of innovation is introduced by Schumpeter with its role in economic development, the concept has been integrated to other fields such as management (Cajaiba-Santana 2014). Although innovation is usually conceptualized with its economic or technological aspects, the social dimension of it started to gain burgeoning interest from the practitioners and scholars with its potential to alter the classical standpoint of government policies and private sector approaches for doing business.

Following the industrialization movements in the nineteenth century, the role of social innovation and social entrepreneurs have become the center of attentions through microcredit agencies, cooperatives, mutual exchange activities, community housing, and etc. (Mulgan 2006). While the concept has been under the attention of scholars since 1980s, its importance was sparked by the OECD (2011) in the aim of highlighting the inadequacy of governmental and market solutions to societal problems. In essence, the ultimate goal of social innovation is to bring wealth to a society through social change which is undertaken by social entrepreneurs (Lettice and Parekh 2010). Social entrepreneurship reflects the process in which social entrepreneurs create and develop a profit or non-profit oriented enterprise in order to initiate social change that can be beneficial for the societies. For instance, Muhammed Yunus who is a globally celebrated social entrepreneur, the founder of Grameen Bank and other microcredit ventures in other countries, started a social change with his social innovation efforts (Mungan 2006). Muhammed Yunus as a social entrepreneur has been aspired to tackle the financial exclusion in poverty-stricken communities through the micro-crediting system which saved ten million people around the world from poverty (Soskin

2012). In this vein, like Muhammed Yunus, the fundamental premise of social entrepreneurs is to serve for societies' problems and needs through social innovations. However, the successful implementation and diffusion of social innovation does not only rely on social entrepreneurs but also the stakeholders who can play a role in building a supportive institutional environment for social innovation adoption and diffusion. Therefore, social innovations require institutional change to solve the societal problems that makes social innovations a complex process to change the fundamental routines in a social system (Westley and Antadze 2010). For instance, since environmental degradation is considered as societal problems, green innovations are considered as social innovations (Dangelico et al. 2013; Howard-Grenville et al. 2014). In terms of institutional support, governments around the world have taken actions through regulations for green production systems, green products, and services. In this process, not only producers but also consumers have adopted the idea that the product they prefer will provide value for them, their society, and their environment as well. Accordingly, the mindset of consumers is transformed in this process of social change which shows that social innovation embodies the involvement of stakeholders including government agencies, universities, local communities, universities, and etc. In line with this view, social entrepreneurs work with stakeholders in order to enhance the mechanisms that can help adoption of social innovation practices to pervade. Therefore, social entrepreneurs need formal and informal institutional support to implement and promote their social innovation practices (Purtik and Arenas 2019).

Related Issues

In addition to social entrepreneurs as the agents of social change, social intrapreneurs also play a role in starting a social transformation. Social intrapreneurship is addressed both at individual level and organizational level. While the individual level addresses the entrepreneurial efforts

of organizational members in an existing organization who seek ways to improve societies' wellbeing, the latter denotes the efforts of existing corporations that focus on societal problems (Alt and Craig 2016; Kistruck and Beamish 2010). Although the conceptualization shows distinction at level of analysis, the concept of social entrepreneurship and social intrapreneurship both address the well-being of a society through employment of social innovations.

As stated before, social innovations have the potential to lead the rise of a sustainable mindset through a network society including informal and formal institutions (Mulgan 2006; Phills et al. 2008). Social innovations address unfruitful systems by generating sustainable solutions for climate change, epidemics, social inequalities, education problems, and other global challenges (Murray et al. 2010). Regarding these issues, the concept of social innovation can be used interchangeable with responsible and sustainable innovation (Lubberink et al. 2017a). This conceptual overlap is considered as the result of the common motive that are societal and environmental problems. However, while sustainable innovation addresses the triple bottom line in which economic, social, and environmental aspects are covered simultaneously, social innovation responds to the double bottom line. In this vein, responsible and sustainable innovation can cover the social dimension of innovation (Lubberink et al. 2017b). Additionally, social innovations contribute to sustainable development with its sustainable consumption mechanisms (Jaeger-Erben et al. 2015; Voorberg et al. 2015). For example, "collaborative consumption" or "sharing economy practices" are the reflections of changes in consumers pattern of consumption. Time banking activities in which individuals exchange their knowledge and experience mutually or carpooling practices are considered as the primary examples for sharing economy practices (Demirel and Payne 2018). Through these practices, individuals can decrease their consumption level of natural resources. Besides, consumers can improve their lifestyles with collaborative consumption practices (Ziesemer et al. 2019).

Another social innovation effort worth mentioning is the movement towards to the development of bottom of the pyramid markets that constitute the two-thirds of the people living in poverty. The bottom of the pyramid refers to the four billion people whose daily income is less than \$2. According to Prahalad (2013), while large companies can serve to those markets, they can eliminate poverty and build a sustainable society through social and technological innovations. They can improve the life conditions in those markets by selling low-cost computers, contributing to education, selling low-cost apps for special skills, and etc. While companies can make profit with their low-cost products by serving a large population, they can also ignite economic development in those countries. In addition, providing basic needs can provide short run benefits, thus, companies go beyond these practices and make efforts to improve and enable entrepreneurial opportunities for individuals that is required for a more sustainable economic development. Social entrepreneurs not only engage in social innovation but also create an ecosystem in which the people in poverty become creators or producer of products and services. All in all, social innovations focus on the well-being of societies by creating a sustainable ecosystem that can yield mutual benefit for all stakeholders.

Summary

Considering the alarming global issues, social innovation plays a crucial role in overcoming the present unsustainable state of societies. Social innovations denote the social change through the support of formal and informal institutions including local communities, governmental agencies, and etc. Social innovations can be initiated by social entrepreneurs or intrapreneurs. Since social innovations are complex to implement and need the support of informal and formal institutions, local communities and governmental agencies should collaborate with social enterprises in implementation and diffusion process. In this vein, social enterprises are dependent on

stakeholders to realize their ideas. In conjunction with this view, social enterprises need stakeholder management capabilities to build and manage sustainable relationships with their stakeholders.

Definition

Social justice is a central obligation of civil society where the measure of the ethical integrity of a society is how it treats its most vulnerable members. Rawls' (1971) theory of justice as fairness in the context of political liberalism has been influential in modern western capitalist societies.

Rawlsian justice is based on the principle that free and rational people accept the rightness of equality for all members of society as the basis for all other agreements, social cooperation, and forms of government. It presumes that justice will be achieved by a redistribution of societal resources to ensure fairness for all. Feminist scholars have criticized his theory for not giving sufficient regard to emotions in his rational ethic of justice and for not asking the question – fairness for whom? Despite the universalist, modernist undertones of his ideas, Rawls argues for international justice for all types of societies. International justice is needed to ensure minimum standards of including people in political decisions and protecting human rights. Rawls explains that justice must not be only a nation-bound concern or the reserve of liberal societies. He extends justice to include the notion of the law of peoples which all decent peoples will uphold, and this includes not being imperialistic or aggressive toward other people.

Introduction

Contemporary understandings of social justice have built upon this scholarship, and yet it remains a complex idea without a universally agreed meaning. It usually refers to the experience of equality, fairness, and well-being of social groups who have been subject to disadvantage and discrimination. Sociologists argue that social justice occurs when people are free from oppression and all forms of violence. Oppression involves socio-personal harm caused by exploitation, marginalization, powerlessness, imperialism, and violence (Young 1990). Oppression exists in the structures or enduring patterns of behavior in society and includes racism, sexism, ageism, classism, and speciesism. It also includes any other pattern of discrimination that becomes institutionalized in a society's systems and in cultural norms and language. Young (1990) argues that social justice occurs when social institutions enable the inclusion of people in decisions that affect them, which is consistent with ideas of participatory democracy. There can be no social justice where there is oppression.

Justice is integral to the aims of a range of professions, including social work, law, environmental science, and criminology. The International Federation of Social Workers regards social justice as a central principle in social work practice that supports the empowerment and liberation of people. The international association for the legal profession promotes peace and justice through law. Environmental activists and criminology scholars are concerned with environmental or ecological justice in relation to natural resource-based development. Social injuries can occur when people's health and well-being are impacted by toxic environments and when there is devastation of ecosystems and traditional cultures (White 2013). The area of green or environmental victimology takes this further with the argument that not only are humans the victims of environmental crime but so too are animals and ecosystems (White 2018).

This is similar to the idea of trans-species social justice where all species are valued as beings with feelings, needs, and rights. In a similar vein, Australian Indigenous knowledge is based on reciprocal relationships between all living beings and the landscape such that humans are the custodians of their fellow beings and the land.

Transnational justice is suggested by scholars and activists concerned with access to resources, rights, and human security issues such as slave labor, child migration, and asylum seekers. Mass movements of people due to exploitation, persecution, or trauma can become entangled in nation-state border protection laws and categorizations that hide dominant power structures. Powerful groups and businesses can use these structures and laws to deny claims to human rights. Examples of human rights that are not upheld are the right to safe and fair work conditions, the right of children to be mobile without being exploited, and the right of all people to seek asylum.

Justice is a central principle in several international declarations that provide umbrella ethics and guidelines which nation-states interpret in their laws and customs. For example, the 1948 Universal Declaration of Human Rights conveys many principles which are congruent with social justice such as:

Article 3. Everyone has the right to life, liberty and security of person.

Article 4. No one shall be held in slavery or servitude; slavery and the slave trade shall be prohibited in all their forms.

Article 5. No one shall be subjected to torture or to cruel, inhuman or degrading treatment or punishment (United Nations 2019).

The link between achieving social justice and human rights is direct, and each is a necessary condition of the other. Human rights include the legal and civil notions of rights; economic, social, and cultural rights; and the rights of groups and countries. Justice is also an underpinning imperative of sustainability in international socio-economic statements and commitments by nation-states in recent decades – including the 2000 Millennium Development Goals and the 2012 Sustainable Development Goals which aim for an end to poverty, the protection of the planet, and efforts to ensure that all people enjoy peace and prosperity.

Nevertheless, claims to social justice have to be struggled for, and even where international conventions and national anti-discrimination laws exist, it cannot be assumed that people's right to be treated justly will be upheld. There are privileged groups with powerful vested interests in maintaining the status quo of society to their own advantage. The global capitalist economic system creates injustice as part of its logic of profitmaking, use of natural resources, impacts on local communities, and movement of capital across national boundaries. The scale and impact of dominant modes of economics call into question the sovereignty of nation-states, their laws, and the adequacy of modernist notions of social justice.

The Sustainability Issue

Social justice is not possible without sustainable development. Sustainable development will not occur without sophisticated notions of social and eco-justice. In turn, a sophisticated understanding of social justice work needs to be backed up by legal protections and the political will of the

people through their governments. The issue is that development in capitalist globalized economies is not sustainable and not equitable with some countries, social groups, and ecosystems bearing the cost more than others. The issue is thought to be addressed by multinational corporations undertaking corporate social responsibility (CSR) to ensure a net positive social value to business operations. CSR is considered to be a necessary part of securing a social license to operate. The impetus for being seen to be practicing CSR has derived in part from the failures of governments and mining corporations that have resulted in often expensive community backlash and in reputational harm. Examples of failures of corporate social responsibility include BHP Billiton and the Ok Tedi mining disaster in Papua New Guinea; CSR Ltd. and the Wittenoom asbestos disaster in the Pilbara of Western Australia; and the class action and financial settlement against building product manufacturer, James Hardie, by victims of asbestos exposure.

Social justice language and practices need centering in matters of sustainable development and management issues. This requires a more refined understanding of social justice to guide efforts to ensure accountability where the extractive industries in particular have adverse impacts on people, animals, and ecosystems. The Rawlsian notion of justice as fairness and the equal distribution of resources is relevant but has not been successful in guiding efforts to rebalance the extremes of business profits and capitalist wealth on an international scale. Fraser (2009) asks – who counts as a subject of justice – and argues for a global or transnational justice that adopts an all-subjected principle. This contrasts with a nation-bound idea of an all-affected basis for justice. At least in theory, it allows for adjudication where there are competing views, rights, and claims. Fraser refers to circumstances of competing views as abnormal justice where there are claims and counterclaims, and it is not necessarily clear who counts and who is deciding who counts. She explains the all-subjected principle of justice as:

What turns a collection of people into fellow subjects of justice is not shared citizenship or nationality, or common possession of abstract personhood, or the sheer fact of causal interdependence, but

rather their joint subjection to a structure of governance, which sets the ground rules that govern their interaction. For any such governance structure, the all-subjected principle matches the scope of moral concern to that of subjection. (Fraser 2009, p. 292)

This approach places social relationships, whether in the form of direct interactions or indirect form through the influence of governance structures, and how power is exercised, at the center of how to respond to justice claims. All parties in a justice issue are to be regarded as equal moral claimants with an equal voice in deliberations about the issue. The reality though can be one of inequality in terms of political influence and financial resources to mount a legal claim for justice in the absence of robust democratic and dialogical methods of settling disputes.

Way Forward: Eco-social Justice for Sustainable Development

Attention needs to be given to balancing the asymmetries of power relations in justice claims in resource development disputes. It is important that deference, preferably enshrined in legislation, is given to the least powerful parties experiencing adverse impacts. This is about impacted stakeholder justice which is inclusive of animal's rights and is consistent with the social precautionary principle and sustainability. However, eco-activists and scholars recognize the limits of relying on international declarations, governments, and legislation to protect the rights of people, animals, and ecosystems. For example, White (2009) argues from an eco-justice stance that there is a need for transnational victims' activism as part of resistance to state crime and environmental harm caused by the extractive industries. White describes state crime in this context as occurring when governments fail to ensure industries operate within the limits of sustainability and when there is insufficient regulation of, and consequences relating to, environmental and other harm. Higgins proposes laws such as a Bill of Nature's Rights and an extension of the Declaration of Human Rights to include Mother Earth as part of what is needed to eradicate ecocide and to hold perpetrators

accountable for the destruction of the planet. She argues that without environmental sustainability, life itself on this planet of finite resources is at risk and calls on the “commanding voice of the people ... to make ecocide a crime” (Higgins 2010, p. 166).

Summary

Social justice requires all forms of sustainability, economic, environmental, and social and has an affinity in particular with social sustainability. Social sustainability refers to a state of human and non-human well-being when social, economic, and environmental factors align to support present time and intergenerational equality and flourishing.

Most western governments have environmental protection legislation which contains an environmental precautionary principle. This is where caution is exercised if there is uncertainty about the risk of harm from a development or expansion proposal. The subjected public can argue against a development that may irretrievably damage the environment or threaten endangered species by using this principle. According to social justice as all subjected, a social precautionary principle is also needed for the protection of the social well-being and assets of communities and for human and animal health. This principle is based on the value of caring for life and the planet.

There are no quick answers or one-size-fits-all solution to unsustainable development. The intersecting interests and issues in any circumstance of injustice involve powerful business and pro-development national governments. It is clear though there can be no social justice without environmental justice.

Definition of Legitimacy

In the field of management, social legitimacy refers to the degree to which the general public and other stakeholders support a specific behavior

or program implemented by a private or public organization. It refers to the social acceptance of organizations (also named organizational legitimacy). One of the first comprehensive definitions is provided by Suchman (1995, p. 574) who describes legitimacy as “a generalized perception or assumption that the actions of an entity are desirable, proper or appropriate within some socially constructed system of norms, values, beliefs and definitions.” In other terms, the concept is socially constructed in that it reflects a congruence between the behaviors of the legitimated entity and the shared (or assumedly shared) beliefs of some social group. Legitimacy depends on a collective audience (evaluators) that approves or supports the company behavior despite a single or particular observer may have reservations or disapprove it. The underlying idea is that companies conclude a kind of “social contract” to run their business that implies congruity between the social values associated to their activities and the commonly accepted rules of conduct in the broader social system they belong to (Cho and Patten 2007). When there is a lack of congruity because society’s expectations are not satisfied, there is a problem of legitimacy that could compromise the above-mentioned contract and consequently hinder company’s credibility and continuity, i.e., making it impossible for the company to obtain the human, financial, and other resources it needs to operate.

The Basis of Legitimacy and Its Classifications

A widespread definition of legitimacy is the one provided by Suchman (1995, p. 574) who defines legitimacy as “a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions.”

Legitimacy theory is rooted in the works of Weber and Parsons (see Dowling and Pfeffer 1975; Sethi 1979) and is classified as a sociopolitical theory as it concerns the relationship between companies and members of the external

society, recognizing that companies influence and are influenced by the society in which they operate (Branco and Rodrigues 2012). There are various sociopolitical theories; among them, institutional theory is the one that mostly emphasizes the relevance of legitimacy. Institutionalists largely believe that the behavior of actors and organizations is guided by the logic of appropriateness and not simply by economic rationality.

However, the process of legitimation stemming from the reciprocal influence between the company and the wider society is not uniquely defined because the way (or criteria) in which societal actors evaluate organizations and their actions can differ.

According to Suchman (1995), legitimacy can be rule-, moral-, pragmatic- or cognitive-based. In the first case, legitimacy is linked to its coherence with rules and laws. In the second case, an activity or company’s behavior is held as legitimate if it is the “right thing to do,” if it is consistent with moral standards (i.e., there is a moral evaluation). In the third case, legitimacy depends on the judgment of close stakeholders or constituencies that assess something as legitimate if it brings a benefit or desirable outcome to the evaluator (i.e., stakeholders themselves). Finally, legitimacy is achieved when there is a take-for-granted assumption within the society that the organization and/or its actions are necessary and inevitable. In this last case, legitimacy stems from cultural models, dominant ideas, and beliefs and does not depend on the evaluation of some group of stakeholders. Similarly, Scott (1995) identified three pillars that sustain the legitimacy of institutions: the regulative pillar that emphasizes legitimacy as a consequence of obedience to nonlegal and legal obligations; the normative pillar that highlights a more ethical basis to obtain legitimacy; and the cultural-cognitive pillar that approaches legitimacy via the adaptation of a commonly accepted framework. These three pillars present the institutional surrounding, which constitutes appropriate decision-making and actions in order to gain legitimacy. Scott’s (1995) regulative Pillar aligns with DiMaggio and Powell’s (1983) coercive isomorphism. The normative pillar provides a more widespread sight although there are similarities

with the work of DiMaggio and Powell's (1983) normative isomorphism (Scott 1995). The cultural-cognitive pillar of Scott (1995) is an equivalent of the mimetic isomorphism of DiMaggio and Powell (1983).

A refined classification of the different criteria used to define legitimacy and the tactics exercised to obtain and then maintain legitimacy is offered by Deephouse et al. (2017). These authors emphasize how legitimacy may stem from different criteria (regulation, pragmatism, ethics, and cultural frameworks that support regulatory, pragmatic, moral, and cultural-cognitive legitimacy) and different sources (the public opinion, the state, the profession, the media, a group of stakeholders, etc.) that evaluate what is legitimate. The interplay of these criteria and sources/evaluators represent the different types of legitimacy.

The work of Deephouse et al. (2017) is also important because it adds the idea of legitimacy as a dynamic process as the evaluation criteria may change over time with the formation of new scenarios, the internal change of organizations and the transformation of society's rules and standards against which company behavior is evaluated. Previous studies conceived legitimacy as a property, resource or thing that is possible to have or they conceived legitimacy as a form of socio-cognitive perception or evaluation. When legitimacy is understood as an interactive process, it means that legitimacy is continuously challenged and organizations need to find the appropriate response. Some organizations will respond by demonstrating appropriateness, or affirming adequate performance or their fit with social values and systems of meanings. However, organizations may also react to a legitimacy challenge by launching activities that change social values and meaning systems or modify (e.g., through lobbying) regulations. In the first case, organizations tend to conform to external pressures, while in the second case organizations strategically act to institutionally innovate the local context.

As stated by Suddaby et al. (2016), legitimacy is an important subject in political science, philosophy, psychology, and sociology. However, its popularity is due to management and business studies.

Business studies investigate the social legitimacy of organizations adopting two different theoretical frameworks that basically represent the origins of legitimacy theory (Spence et al. 2010). One group of studies rely on the institutional approach. These institutional based studies focus on how situational aspects that are external to the firm generate pressures influencing company behaviors and actions. The other group of studies rely on resource dependence theory. These are strategic oriented studies that conceive legitimacy as something that managers can manipulate and therefore focus on how companies can obtain a key resource, namely societal support. Within the institutional approach, legitimacy is considered as a set of constitutive beliefs, which are adapted to conform to external expectations about what is acceptable. When this framework is adopted, investigations regard the process by which institutions construct and interpenetrate organizations (DiMaggio and Powell 1983; Meyer and Rowan 1977) and attention is given to external actors that exert pressures on companies like government authorities (Ahmed Haji 2013; De Villiers and Van Staden 2006; Deegan and Rankin 1996) and nongovernmental organizations (Deegan and Islam 2014). When resource dependency theory is preferred, legitimacy is considered as an operational resource on which the organization is dependent for survival (Dowling and Pfeffer 1975). Preference for this second framework leads authors to assume the perspective of company managers "looking out" to the society and to focus on how companies try to alter their status of legitimacy through disclosure and communication strategies (Ashforth and Gibbs 1990; Aerts and Cormier 2009).

Legitimacy and CSR

Legitimation is one of the three key motivations that drive firms to adopt socially responsible practices or a sustainable behavior. According to Bansal and Roth (2000), firms adopt corporate social responsibility (CSR) practices either to gain competitiveness or to obtain legitimacy. In the first case, company's behavior rests on

self-interest and aims to efficiency and efficacy. CSR is a mean to achieve organization's goals. In the second case, company's behavior is influenced by values and beliefs in the society as companies aim "to gain the license to operate and goodwill in the public eye" (words of Podnar and Golob 2007, p. 336).

Legitimacy or social legitimacy is also one of the most commonly used theories to explain the disclosure of CSR practices through sustainability reports or other media (Campbell et al. 2003). While some authors attribute more emphasis to other theoretical explanations (Guthrie and Parker 1989), many authors confirm legitimacy theory as the primary explanation for social reporting.

Legitimacy theory ascribes the adoption and reporting of CSR practices to the external pressure that a society places on companies, which can activate communication strategies in order to acquire, maintain or reconquer the legitimacy of their operations (Cho and Patten 2007; Darrell and Schwartz 1997). In other terms, CSR practices and sustainability reporting can be the result of a company's attempt to be compliant or comply with external pressures. However, reporting can also be used as a tool of strategic adaptation (Gray et al. 1995). In the latter case, CSR is a strategy adopted to legitimize corporate existence and this is evident when the company deliberately emphasizes on a given form of CSR beyond some threshold level needed to satisfy explicit demands.

Empirical investigations on the relationship between CSR and the achievement or maintenance of company legitimacy span through different sectors. A large amount of studies has explored the use of socioenvironmental reporting to gain legitimacy by polluting companies like those operating in the oil and gas sector (Islam and Islam 2011). These companies work in a controversial industry frequently criticized for issues ranging from environmental violations, to human rights abuses, detrimental impact on local communities, and breaches of labor and safety standards. Therefore, their organizational legitimacy is often being challenged (Palazzo and Scherer 2006). There are also many studies investigating how CSR disclosure can be used to recover the loss of legitimacy after an industrial

disaster or scandal caused by a company (Summerhays and De Villiers 2012; Aureli et al. 2016; Demajorovic et al. 2019). High-profile disasters, such as the Exxon Valdez oil spill in 1989 and BP's oil spill in the Gulf of Mexico in 2010 are remarkable examples. However, the use of CSR as a device to maintain legitimacy with key constituents (audiences) can refer to almost all industries and types of companies, including accountancy firms (Duff 2016, 2017).

Since legitimacy issues emerge because of negative media publicity and the increased level of stakeholders' sensitivity to ethical, social, and environmental issues (Maignan and Ferrell 2004), many authors also investigate the role of media in creating negative public sentiment. The media agenda setting theory states that media generate awareness of the event or disaster in the community and their news create pressure on companies. Therefore, the number and type of articles in the media must also be studied (Deegan and Islam 2014). This approach differs from previous studies that associate media with the most influential stakeholders (Brown and Deegan 1998). In the latter case, it is argued that the pressure of the media is the expression of – and therefore perfectly fit to – the pressure of a specific social group. On the contrary, the media agenda setting theory claims that media's role is to attract the attention of the public; consequently, the opinion of the media is not necessarily the same as that of the public (Gillet-Monjarret 2015).

The disclosure of CSR information to gain legitimacy is not standardized. Companies do not pursue the same communication strategy: some may opt for an image enhancement strategy, others may deny responsibility for the events (disclaimer strategy), and others may choose an avoidance strategy, aiming to distract public attention from a given event or situation which could damage the organization (Summerhays and De Villiers 2012). In addition, the usage of sustainability or social reports is only one of the possible strategies that a company adopts to gain or maintain legitimacy. As found by Cho (2009), an organization can implement different strategies to face the same event happened in two different moments. In general, companies may opt for two

different types of strategies: symbolic actions (i.e., practices that enable the company to pursue its own interests and preserve its resources) or through substantive practices (i.e., they initiate a legitimization strategy that may compromise the company's own interests and resources) (cf. Ashforth and Gibbs 1990).

Summary

The adoption of CSR practices and their communication to the society is widely acknowledged as a means to obtain legitimacy. However, some researchers have recently offered a contrasting view; for example, Bachmann and Ingenhoff (2016, 2017) suggest that CSR disclosures can also decrease a company's legitimacy, because stakeholders may become skeptical and distrust company's narratives.

Accountability; Community engagement; Corporate social responsibility disclosure; CSR; SLO; Sustainable environments

Description

Local communities in the developed economies realized that the operations of environmentally invasive industries would lead to certain benefits to their neighborhoods but increasingly needed persuading these were worth the negative consequences. Their concerns typically include but were not limited to: increased levels of pollution and the potential resulting impact on public and employees' health, changes in the nature and composition of the community, the impact on existing local businesses and the economy in general, restricted access to services, and overall impact on their quality of life.

Bowen's seminal work on corporate social responsibility (Bowen, 1953; Gond & Moser 2021; Cornelius & Wallace, 2023) and the later introduction of stakeholder theory (Freeman, 1984) led to the realization of the need for greater accountability and compensation for these negative impacts for those directly and indirectly affected communities. In the late 1990s, the mining industries introduced the concept of a **social license to operate (SLO)** as an active part of their corporate social responsibility to stakeholders of their operations (Gunningham et al., 2004), to address these concerns. Since then, SLOs have become an integral part of the continuing approval process by stakeholders of ongoing mining operations at existing mines and for newly proposed sites (Prno & Slocombe, 2012; Thomson & Boutilier, 2011).

It is seen as a collaborative arrangement between the industry and stakeholders to sanction agreed operations, to encourage sustainable developments, and to agree compensatory measures that the industry can take to benefit affected communities and assuage unavoidable negative consequences. In the absence of an agreed SLO, and even when required legal permissions have been obtained from regulatory bodies, communities can still resist such developments. The consequences to the reputation and brand of the organization by operating under these circumstances can be substantial and difficult to remedy. The potential increases in operational costs could also be sizeable. As such, an SLO is seen as a

flexible way forward for society and so has been, and continues to be, introduced in diverse industries and novel operational settings. Although not necessarily a panacea for resolving inevitable conflict between stakeholders and organizations in all situations, it does provide a rational basis for dialogue, leading to an agreed SLO with overall benefits to both parties, albeit typically after suitable compromises. Table 1 provides an indicative list of such industries:

As mentioned, one of the major strengths of the SLO is its flexibility. It is not required to be a formal signed document, but as Bice (2014), Black (2017), and Parsons and Moffat (2014) argue, it is a metaphorical concept. It can comprise a signed legal license from an appropriate regulatory authority, should this be required, and a social license sanctioned by shareholders. The latter is rarely a signed document (Baumber, 2018; Franks & Cohen, 2012) but rather a tacit agreement with various stakeholder groups regarding operating practices, schedules, and any mitigating compensatory provisions that might be agreed. These can be unrelated to any immediate consequence of the operations or activities of the organization and more designed for social value creation within or beyond the affected communities. For example, sponsoring regeneration of derelict local infrastructures, to providing a school in a remote rural area of a developing economy. Furthermore, the proposed activity by the organization might have overall significance to a greater constituency of stakeholders, e.g., nuclear power-generating plant construction and commissioning, building wind turbine parks, hydraulic fracturing (fracking) for extraction of shale gas and oil, coal seam gas (CSG) mining, etc. This flexibility and the need for specificity have prompted the existence of multifaceted, multiple forms, of SLOs (Brueckner & Eabrasu, 2018; Gough et al., 2018; Hurst et al., 2020) that accommodate individual projects, specific industries, or even those proposed by particular organizations. As Luke, Brueckner, and Emmanouil (2018: 648) observe: “[. . .] industry-community conflict situations and the heterogeneity of social license outcomes.” They may also address projects that operate at the local, district, regional, national, or

even international levels (Parsons & Moffat, 2014).

It is argued (e.g., Dare et al., 2014; Esteves & Vanclay, 2009; Hurst et al., 2020) that, in addition to ongoing access to resources, the benefits to the organization of obtaining a social license to operate include the following: increased reputation

among stakeholders through legitimacy, trust, and credibility; an increase in competitive advantage in the market place; and, positive effects on its employees.

The pragmatic flexibility for social license(s) to operate as a concept led to the evolution of three distinct main models for this initial acceptance and ongoing sanctioning: the Triangle model; Pyramid model; and the Three Strand model. For each model, legitimacy and trust are central and critical to achieving sustainable and socially acceptable outcomes for stakeholders.

The Triangle Model

The Triangle model (Wüstenhagen et al., 2007) represents a social license to operate predicated on, and a consequence of, acceptances by stakeholders in three fundamental domains: the socio-political and legal, that of the affected community, and the specific market in which the operations/activities are planned to take place (see Fig. 1). The rationale is that acceptance in these distinct domains will signify overall social acceptance and will lead to legitimacy for both the vendor and the specific project, or venture, under scrutiny. Its origins stem from the renewable energy industry.

The socio-political/legal domain requires acceptance by the public, including germane and critical stakeholders, policy makers, and

regulatory authorities regarding the proposed operating processes and procedures, and use of any proposed technologies. Community acceptance requires stakeholders to accept and trust that they will be afforded procedural justice and distributional justice regarding all operations and activities. Finally, market acceptance requires acceptance by the public at large, funding and regulatory authorities, the local communities, the vendor’s employees, and consumers.

Once these have been achieved, a social license will tacitly be in place.

The Pyramid Model

The Pyramid model was introduced by Boutilier and Thomson (2011) and was initially developed for the mining industry but has a greater currency, given the expansion of the concept into other industries. The model considers there to be a hierarchy of four distinct stages of acceptance in a social license to operate. These represent the degrees of acceptance for a project and start at the point of an initial proposal being withheld or an ongoing one failing and having its social license being withdrawn. It introduces the psycho-social conditions (legitimate, credible, and trustworthy) required to transition through these levels.

The basal level of acceptance can be reached by the organization achieving legitimacy among

Social License to Operate, Fig. 3 Pyramid Model of social license to operate: four components. (Adapted from Boutilier & Thomson 2011)

stakeholders for the project. Approval follows with the organization achieving credibility with trust finally leading to psychological identification (Pirson & Malhotra, 2011). A schema for the Pyramid model is exhibited in Fig. 2.

The social license also has a corresponding set of four components that the organization needs to

provide to establish acceptance from stakeholders (see Fig. 3). Black (2017) suggests that these can be considered as strategies for developing or improving - establishing, maintaining or Improving) - a social license that an organization must follow.

Providing legitimate benefits for stakeholders is seen as essential. For the social

Social License to Operate, Fig. 4 The Three Strand Model. (Adopted from Morrison, 2014)

license to operate to be more robust and sustainable, the organization should increase its social contract together with its social capital with affected stakeholders. These can be achieved through authentic and ethical engagement and can lead, ultimately, to mutual trust between the organization and its stakeholders.

The Three Strand Model

The third major social license to operate model in the literature is the Three Strand model. Following empirical research undertaken by Gunningham and coworkers, a multiple-faceted license model was identified. This comprised: a regulatory license, one based on a social license, and an economic license (Gunningham et al., 2004). The regulatory license required appropriate sanctioning by the project being compliant with

international and local legislation, any additional regulations governing the specific industry, and where deemed appropriate, acceptance by magistrates or judges. For the social license, acceptance is needed from a variety of stakeholders, including those affected in the immediate vicinity of the venture, a wider constituency of relevant pressure groups, the general public, international environmentalists, etc., depending on the particular nature of the project. The economic license also needs acceptance by all streams of funders and management from the proposing organization. Subsequently, Morrison (2014) introduced the Three Strand model in which the economic license is replaced by a political license dimension with Van Putten and coworkers (2018) arguing that, in practice, this does not substantively change the acceptance of the social license to operate. This was universally accepted and represents the currently proposed Three Strand model (see Fig. 4).

Social License to Operate, Fig. 5 Social license to operate models hierarchy. (Adapted from Van Putten et al., 2018)

Summary

Despite differences to accommodate the nature of the proposed project, the three social license to operate models (Triangle, Pyramid, and Three Strand) embrace the three necessary key components of legitimacy, credibility, and trust, albeit in varying degrees (Van Putten et al., 2018). This hierarchy is represented, diagrammatically, in the schema in Fig. 5.

Social Life Cycle Assessment

Elisa Baraibar-Diez, Ignacio Llorente and
María D. Odriozola
University of Cantabria, Santander, Spain

Synonyms

[LCA](#); [Life Cycle Assessment](#); [S-LCA](#)

Introduction

The concept of Social Life Cycle Assessment (S-LCA) cannot be understood without first talking about its antecedents, since it is closely linked to the concept of Life Cycle Assessment (LCA) or Life Cycle Analysis. The concept of life

cycle has a biological origin as it considers the changes in the life of an organism. The definition of life cycle is “the series of stages in form and functional activity through which an organism passes between successive recurrences of a specified primary stage” (*Life Cycle | Definition of Life Cycle by Merriam-Webster*, 2021). Translating that life cycle concept into a business context, product life cycle involves managing, especially from a decision-making point of view, at all stages of the product’s life: introduction, growth, maturity, and decline. This business approach is usually called Product Lifecycle Management (PLM). Life cycle assessment, instead, is a methodology that assesses the environmental impacts generated by a product, from raw materials to the possible recycling afterwards. From the 1970s, the interest in assessing the environmental impact of production processes began to emerge. In the 1990s, there began to be references in the literature about the specific social impact of products, that is, how humans are affected by products or systems (Jorgensen et al., 2012), with which the independent concept of S-LCA began to be used. In the last 20 years, there are two clear turning points that have revolutionized the analysis and development of S-LCA, both enhanced by “Life Cycle Initiative,” a “public-private, multi-stakeholder partnership enabling the global use of credible life cycle knowledge by private and public decision makers” (*Life Cycle Initiative*, 2021) hosted by United Nations Environment Programme (UNEP). In this sense, UNEP/SETAC Guidelines for Social Life Cycle Assessment of Products in 2009 marks a before and an after in the implementation and development of the S-LCA. In 2013, Methodological Sheets for Subcategories in Social Life Cycle Assessment (S-LCA) are released to supplement the Guidelines by providing detailed information on each of the subcategories by stakeholder category (United Nations Environment Programme (UNEP) & Society of Environmental Toxicology and Chemistry (SETAC), 2013). This approach does not seem to be so closely linked to the production process itself but to the conduct of the company (Jorgensen et al., 2008), which has broadened the scope in which S-LCA has an interest:

investment, design, industrial management, consumers, or public decision-making (Jorgensen et al., 2008). In fact, the concepts “social” or “societal” are used in a generic and indeterminate way, making it necessary to clarify the concept with precision when selecting and defining indicators (Grießhammer et al., 2006). In recent years, there are several bibliometric analyses and reviews that delve into this field of research, such as those of (Huertas-Valdivia et al., 2020; Petti et al., 2018; Wu et al., 2014). In this entry, we briefly review the definition of Social Life Cycle Assessment, as well as its evolution and productivity in the literature. Later, we will include the S-LCA framework. Finally, we will highlight the key issues and future directions for Social Life Cycle Assessment.

Definition

The Guidelines for Social Life Cycle Assessment of Products (2009) defines Social Life Cycle Assessment (S-LCA) as a “social impact (and potential impact) assessment technique that aims to assess the social and socio-economic aspects of products and their potential positive and negative impacts along their life cycle encompassing extraction and processing of raw materials; manufacturing; distribution; use; re-use; maintenance; recycling; and final disposal” ((United Nations Environment Programme (UNEP) & Society of Environmental Toxicology and Chemistry (SETAC), 2009). This is the most widely used definition, although other authors extend the scope of action to communication and consumption. Thus, Norris et al. (2014) propose that S-LCA is “a technique for collecting, analyzing and communication information about the social conditions and impacts associated with production and consumption” (Norris et al., 2014). In any case, there is consensus between the consideration of current and potential impacts as well as the consideration of positive and negative impacts. The goals of S-LCA approaches are product, process, or company comparisons and product or process improvement potentials (Jorgensen et al., 2008), as well as the improvement of the social

conditions for the stakeholders affected by the assessed product’s life cycle (Jorgensen et al., 2010).

Social Life Cycle Assessment in Literature

The consideration of social and socioeconomic criteria in LCA began in 1993 with the report by Fava et al. (1993) entitled “A Conceptual Framework for Life Cycle Impact Assessment,” but it was not until 10 years later that it appears as a concept in “Life-cycle based methods for sustainable product development” by Klopffer in 2003. The qualitative leap occurred in 2008, when the article “Methodologies for social life cycle assessment” written by Jorgensen et al. (2008) was released, endorsed by the publication of the Guidelines for Social Life Cycle Assessment of Products in 2009 by the United Nations Environment Programme (UNEP) and the Society for Environmental Toxicology and Chemistry’s (SETAC). As of this moment, the production of articles related to S-LCA begins to emerge. The next turning point is also marked by the publication in 2013 of Methodological Sheets for Subcategories in Social Life Cycle Assessment, also by UNEP and SETAC.

Figure 1 shows the evolution of papers in Web of Science Core Collection with the following search criteria (May, 2021): “Social life cycle assessment” OR “Social life-cycle assessment” OR “SLCA” OR “S-LCA” OR “Social-LCA” OR “Social LCA,” filtered by articles.

Considering the years of publication of the Guide and the Methodological Sheets (2009 and 2013), productivity in the 2014–2021 period is five times higher in articles related to S-LCA in the topic (title, abstract, and keywords) and six times higher in articles related to S-LCA in the title (Table 1).

In the last few years, several authors have focused on the state of the art of social life cycle assessment (SLCA). To date, the last available bibliometric review is that of Huertas-Valdivia et al. (2020), which includes

Social Life Cycle Assessment, Fig. 1 Evolution of articles with the concept “Social Life Cycle Assessment” in the topic and in the title (Web of Science Core Collection). (Source: Authors)

Social Life Cycle Assessment, Table 1 Evolution of S-LCA articles in web of science core collection by period

	Up to 2008	2009–2013	2014–2021

previous papers classifying contributions and identifying approaches (Arcese et al., 2018; Bonilla-Alicea & Fu, 2019; Iofrida et al., 2018; Jorgensen et al., 2008), understanding definitions (di Cesare et al., 2018) or providing a more comprehensible picture of S-LCA (Solene Sureau et al., 2018). After Huertas-Valdivia et al. (2020), only one contribution is devoted to past and future of S-LCA (Ramos Huarachi et al., 2020). During the entire period but especially since 2013, most of the papers focused on case studies in which the application of the S-LCA is analyzed. In this sense, Petti et al. (2018) reviewed that 26% of case studies were applied to manufacturing and 26% in agriculture, followed by 24% of case studies applied to energy sector and 21% applied to waste management sector, identifying only one case study dealing with tourism. Regarding the geographical area, 48% of case studies are implemented

in developed economies and 46% developed economies (Petti et al., 2018).

The *International Journal of Life Cycle Assessment* leads the ranking of journals with 128 articles through May, 2021. In the last 3 years, *Sustainability* has risen in the ranking proposed by (Huertas-Valdivia et al., 2020), equaling the following journal in the ranking, *Journal of Cleaner Production*. Articles in these two journals triple the next journals on the list (Table 2).

Top nine authors who have contributed more articles on S-LCA are Matthias Finkbeiner, Marzia Traverso, Anne Katrin Lehmann, Michael Zwicky Hauschild, Anna Irene De Luca, Andreas Jorgensen, Luigia Petti, Jean-Pierre Reveret, and Alessandra Zamagni, mainly from technical universities (Berlin, Aachen, and Denmark) and one author from a research spin-off, Ecoinnovazione (Table 3).

Social Life Cycle Assessment Framework

Delving into social impact assessment methodologies exceeds the purpose of this entry, but it must be said that S-LCA coexists with other methodologies such as Cost Benefit Analysis (CBA), Social Return on Investment (SROI), Social Impact Assessment (SIA), and social accounting, among

others. Each of them responds to different goals and contexts. In the S-LCA framework, the integration of social issues gives more priority on the process and the integration of stakeholder positions and on the treatment of product utility (Grießhammer et al., 2006), describing the corresponding social and symbolic functions for the consumer.

The methodological framework of the SLCA includes the following: (1) goal and scope definition, (2) inventory analysis, (3) impact assessment, and (4) interpretation (Grießhammer et al., 2006):

1. Goal and scope definition. In addition to the goal of the study (i.e., product development, comparative purposes) and the scope and boundaries of the issue, the temporal scope must be determined. Once these settings have been determined, the appropriate indicators to reach that goal are selected.
2. Inventory analysis/life cycle inventory. At this stage, relevant information identified during the scope definition is collected. In this way, a balance must be found between the administrative advantages of using generic data and its lack of specificity (Jorgensen et al., 2008).
3. Impact assessment/life cycle impact. At this stage, information is translated into impacts, containing its classification, characterization, and normalization and valuation of impacts.
4. Interpretation of results, and evaluation. The interpretation includes several checks such as completeness, consistency, sensitivity, materiality, and responsiveness.

The Guide to the Methodological Sheets states that social life cycle impact assessment (stage 3) “is the process by which inventory data is aggregated within subcategories and categories.” This guide considers two types of impacts (p. 8):

- Type 1/Type I. These impact categories rely on internationally accepted levels of minimum performance and use scales describing risk, performance, or the degree of management.
- Type 2/Type II. Categories that represent the impact pathways or cause-effect chains, using quantitative data. In the taxonomy for social impact pathway indicators, the guide suggests three levels: elementary flows, midpoint impacts, and end-point impacts (Weidema, 2020), inherited from ISO 14040 series for Life Cycle Analysis. Elementary flows divide into biophysical pressures, economic pressures, and social pressures, each of it having different levels. For example, the level “Economic pressures” (level 1) divides into “Human time (labour & leisure hours),” “Insufficient payment of labour or taxes,” and “Monetary expenditure, except wages” (level 2). At the same time, “Human time (labour & leisure hours)” divides into “Labour hours” and

“Leisure hours” (level 3) (Weidema, 2020). The use of different levels of indicators: Midpoint and end-point indicators can indicate causal-effect relationships (Wu et al., 2014).

Jorgensen et al. (2008) establishes that the formulation of indicators must first consider nature (quantitative, semiquantitative, and qualitative) and second the capacity for measuring direct or indirect impact (through proxy measures). He reviews the highest frequency for indicators in 11 papers, classifying them into qualitative or descriptive indicators:

- Human rights: nondiscrimination, freedom of association, and collective bargaining; child labor; and forced and compulsory labor
- Labor practices and decent work conditions: wages; benefits; physical working conditions; psychological and organizational working conditions; and training and education of employees
- Society: corruption, development support and positive actions toward society; local community acceptance; and ensuring of commitment to sustainability issues from and toward business partners
- Product responsibility: Integration of customer health and safety concerns in product; information about product to users; and marketing communications

A few years, later, there begins to be relative consensus in the groups of stakeholders used, so that social and socioeconomic impacts may be observed in relation with five main stakeholder categories: workers/employees, local community, society (national and global), consumers, and value chain actors (Benoit et al., 2010). These are the groups of stakeholders used in the Methodological Sheets, with several assessment subcategories. Each sheet includes the definition of the subcategory, its relevance to sustainable development, international conventions and agreements, recommended standards, data needed to compile the subcategory, data availability and sources, generic and specific indicators (inventory indicators, units of measurement, and data

sources/methodology), and limitations and references (Table 4).

Key Issues and Future Directions

Authors in literature agree that one of the barriers in the development of S-LCA is the lack of clarity in its definition. Sometimes, the goal and scope of S-LCA is misunderstood with that of Corporate Social Responsibility (CSR). Unlike CSR, S-LCA has developed a framework, but the application varies due to the lack of standardization (Tsalidis et al., 2021). Thus, despite attempts at homogenization, it is still a challenge to obtain a comprehensive set of indicators that cover social issues in all settings (Grießhammer et al., 2006), and that is why it is so important to promote research and the use of theoretical models to identify pathways that seek to explain relevant phenomena in S-LCA (Solène Sureau et al., 2020). In fact, not only the use of theoretical frameworks but also the use of more formal analysis methods, such as multivariate analysis, will help to understand the cause-effect chains in the impact pathways.

It is necessary to clearly define each indicator in its context, differentiating between obligatory (more general) and optional (more adapted) indicators connected with other indicators in the field of CSR (namely, GRI, SA8000, etc.) (Grießhammer et al., 2006), improving the social sustainability considerations for less developed stakeholder groups such as consumers or value chain actors (Tokede & Traverso, 2020). The lack of publications in the field of management also shows one of the future directions in research on S-LCA. If we want to promote sustainability management in companies, conducting more case studies is needed in management journals that disseminate the S-LCA framework as a tool to support decision-making.

In the last 5 years, LCA and S-LCA have evolved toward Life Cycle Sustainability Assessment (LCSA), under the formula of $LCSA = LCA + LCC$ (Life Cycle Costing, indicating the coverage of all costs during life cycle) + SLCA (Wu et al., 2014; Finkbeiner

Social Life Cycle Assessment, Table 4 Categories and subcategories used in the methodological sheets for sub-categories in S-LCA

Local community	Value chain	Consumer	Worker	Society
Delocalization and migration Community Engagement Cultural heritage Respect of Indigenous rights Local employment Access to immaterial resources Access to material resources Safe and healthy Living conditions Secure living conditions	Fair competition Respect of intellectual property rights Supplier relationships Promoting social Responsibility	Health and safety Feedback mechanism Privacy Transparency End-of-life responsibility	Freedom of association and collective bargaining Child labor Fair salary Hours of work Forced labor Equal opportunities/discrimination Health and safety Social benefit/social security	Public commitment to sustainability issues Prevention and mitigation of conflicts Contribution to economic development Corruption Technology Development

Source: UNEP/SETAC (2013)

et al., 2010). LCSA refers to the evaluation of environmental, social, and economic impact and benefit of a product throughout its life cycle, aiming to accommodate knowledge from different disciplines (Zamagni et al., 2013). The creation of a common assessment technique from different sustainability concepts and tools, such as LCSA proposes, may be the path to finally provide an integrated and standardized framework to analyze and promote the environmental, social, and economic aspects for the development of sustainability impact management.

Summary

SLCA is a technique that assesses both social and socioeconomic aspects of products, as well as their positive and negative potential impacts along their life cycle. The aim of SLCA is to compare products, processes, or companies, but also to detect improvement potentials, not only in the product or in the process but also in the social conditions. The focus on the integration of social issues on the process and on the product is one of the characteristics regarding other impact assessment methodologies, such as Cost Benefit Analysis (CBA), Social Return on Investment (SROI),

Social Impact Assessment (SIA), or social accounting.

Introduction

In a globalized world like today, the human being becomes more and more the reason and motive for the main policies of the State. On the basis of this reality, social organizations take over from states in the equitable, sustainable, and democratic development of human rights by becoming actors of social change.

To respond to these objectives, society supports various projects to promote its positive development in order to build a public value beyond the individual and private interest of each agency or individual. However, in order to manage these values, we must seek solutions that, while delimiting their field of action, serve to develop the different actions with which the human being achieves their objectives. In this sense, the term social management serves to respond to the construction of various spaces that encourage social interaction.

Definition

The term social management etymologically consists of words that come from Latin. First, there is the word “social” that has its origin in the Latin word *socius* which is equivalent to “friend.” Second, the English verb “manage” comes from the Italian *maneggiare* (to handle), which derives from the two Latin words *manus* (hand) and *agere* (to act).

However, the concept of social management cannot be reduced to the sum of the elements of the two isolated concepts: social + management. “Social” refers to the field in which it is applied, while “Management” explains strategy, direction, and leadership. However, in the sector for which we are going to use it, the concept of social management is related to the strategic direction that must be given to the economic, political, and cultural aspects (Palacios 1994).

Nevertheless, at the time of its analysis it should not be forgotten that a concept can be examined through its meaning, which results in its identification with a subject. In turn, a concept gives cognitive meaning to an abstract idea in

relation to a context expressed in verbal or written language. Finally, to fulfill the objective that the concept must obtain, it must answer three questions: nature (what it is), scope (how is it used), and purpose (what it is for).

From all of the above, it can be inferred that social management is not identified with a single concept since it is under construction and must be validated by practices in different contexts. That is why, there are authors who prefer to give approaches rather than finished and fixed definitions or concepts. For example, we can talk about a public approach, social development, social policy, social innovation, social inclusion, or efficiency (Parra 2014).

Social management is a complete process of actions and decision-making, ranging from the study and understanding of a problem, to the design and implementation of proposals with a social purpose.

Social management is a set of mechanisms that promote social inclusion and effective community engagement in social projects. It allows subjects to cultivate a sense of belonging, citizen participation, and social control in order to improve society.

In short, social management can only be defined through small, clear, and specific concepts based on a strategy that develops the criteria of equity, efficacy, efficiency, and sustainability. All this allows to guide the decision-making, the actions to be followed, and the control and evaluation of the results achieved.

Social management is therefore an ever-evolving concept that, unlike general management, has a key element: the construction of public value.

Social management puts social profitability before economic profitability with the ultimate objective of solidarity. In this sense, social management is not only concerned with the equitable distribution of economic income, but also concerned with the conservation of the environment, and the implementation of equality policies.

Finally, social management fuses the theoretical framework with learning from experience, thus producing its own view of problems.

Factors That Determine Social Management

On the basis that social management is a developing process, it is necessary to take into account the existence of different factors:

(a) Learning

Social management involves the development of collective, continuous, and open learning through which the community incorporates all those elements that improve its activity. Thus, for example, aspects related to the environment, which were not taken into account in the 1980s, are today protagonists in the management of any company or entity.

(b) Projects

All social management is linked to a project that aims to meet the needs and social problems of a community. To do this, it uses actions and ideas that are interrelated and carried out in a coordinated manner with the intention of achieving a goal that contains social objectives.

(c) Dialogue

Social management implies the need of dialogue between the different communities present in society; hence the joint action of public power, companies, civil organizations, and citizens is necessary. At the same time, it is about creating open spaces in which different disciplines intervene. For example, social management is carried out with elements that come from law, social work, education, economics, and anthropology among others (Fantova, 2005).

This dialogue favors the joint and continuous learning of all these social groups, which allows them to influence the design of public policies. It is, in short, the construction of a space of social relationship and institutional links that is achieved through a set of actions. In this way, social management constitutes a channel through which society acts with an entrepreneurial spirit to

promote social change (Orrego Correa & Arboleda Álvarez 2006).

To achieve the expected results, it is necessary to strengthen community ties and work for the recovery of cultural identity and the collective values of the community on which changes are to be made. This leads to the development of social management using different elements:

- **Coresponsibility:** All actors recognize that they play a part in the responsibility of solving a social issue or problem, which does not imply that they have full responsibility.
- **Multipolarity:** The actors are diverse and think differently. The social causes are diverse, and no one can claim to manage everything or everyone, because each one has his own ideas.
- **Participatory management:** The strength of a social management is in the participation of the actors in it, although not everyone participates in the whole process or to the same degree, but a clear participatory path from design to evaluation can be established in the program or project.
- **Concertation:** No one can impose. It is about mutually agreeing on the best ways and tools through practical forms such as consensus, agreements, coordination, or agreements. Concertation implies that each actor contributes something that is their own, resulting in the sum of efforts of the different actors.

Keys Issues

Effective social management involves knowing recognized social rights and the public system that administers them within a complex framework in which the political, economic, and social dimension of the human being interacts.

Activities Related to Social Management

Given the broad scope of social management, there are very close activities or even essential elements in order to achieve good results in some cases. This would be the case of what is

known as self-management and community development (Parra & Porta 2014).

- **Self-management:** It is a process through which the individual capacity of a human being or a group is developed, identifying their basic interests and needs through an organization. Self-management is self-directed and coordinated with the interests and actions of other groups. This concept implies planning, participatory democracy, and sustainable development.
- **Community development:** It is a process where members of a community come together to take collective action and generate solutions to common problems. It is a broad term that serves to define the practices of civic leaders, activists, and committed citizens to improve various aspects of communities with the aim of building stronger local communities.

Social Marketing

Milan Todorovic

Guildhall School of Business and Law, London Metropolitan University, London, UK

Synonyms

[Health and values marketing](#); [Health-oriented marketing](#); [Marketing for the reaching of common good](#); [Marketing of cultural objectives](#); [Marketing of the social good](#); [Promoting socially engaged subjects and goods](#); [Public service and/or public information campaigning](#)

Definition

The practice of utilizing marketing programs, tools, methods, and procedures for “social good.” Its focus and aim are betterment, influence, and effective behavioral change in the public interest. Social Marketing is especially relevant in the fields of health, well-being, and positive social change.¹

The internal terms of reference (“inherent”, “central” or “primary” may be too a strong a phrase here), defining *Social Marketing* and related practice can be seen as somewhat intrinsically contradictory: This, as they aim to utilize the tools normally employed in commerce and for profit-making to be implemented in attaining greater good and the enactment of positive cultural change within societies. The ambition of this well-established, composite discipline tends to be

¹Kotler and Zaltman (1971) offer a far more comprehensive definition in their seminal text; many subsequent texts compete for attention. Still, this entry opts to offer the most straightforward reading at the opening.

ever more far-reaching and works on a very large scale (with globally expanded programs at times), as some of its more recent practice tends to show.

Evolving aspects of Social Marketing include increasing connections between state actors, public services, and large privately owned businesses including corporations. Public-private partnerships (PPP) in Social Marketing can be traced to well before the term (PPP) was coined within policy (e.g., Parker et al. 2019; Walsh et al., 1993). Partnerships between state and supra-state actors and for-profit organizations appear to be on the increase in Social Marketing. This includes pharmaceutical companies, media organizations, marketing firms, and, more recently, tech giants.² Matters of debate within the field and subject of Social Marketing³ include setting adequate preferences between large-scale and targeted approaches; the ethics and impact of its practice; and the scope and effectiveness of it.

Introduction

To date, social marketing for public health remains the most developed aspect of its practice. Hence the considerable attention was given here. Referred to by Walsh et al. (1993: 106) as key authors who defined the concept of social marketing in health: Codifying the field were Kotler, Manoff, Fine, Novelli, Lefebvre, and Flora. Origins of the modern-day theory and practice of social marketing may be traced back to the early 1950s (if not earlier). The first known, formally articulated mention of the actual practice of social marketing found in an academic text on business practice can be traced back to Wiebe (1951). His paper, "Merchandising Commodities and Citizenship on Television" poses the question of

utilization of business practice for the greater societal, common good.

Wiebe clearly addresses the marketing and media communities at a time when Public Service Announcements (PSAs) were already in use in American television. Practices that utilize media for policy announcements and reinforcement of policy messages aimed at the public can be traced decades back across the world and can be said to have originated in the fields of propaganda, followed by then nascent public relations in the early twentieth century (Bernays 2005: pp. 135–140) [note: Bernays' seminal work was originally published in 1928].

Relatively marginal to the contemporary field of social marketing, PSAs, PIFs, and similar information formats were the media contents attracting Wiebe's attention, giving rise to his critical work.⁴ The matters of PR, Public Service Announcements (USA), Public Information Films/Campaigns (UK), and other related media approaches would be worth revisiting below. To the complement and aid of the discipline, elements of media advertising and persuasion methods continue being utilized where needed (e.g., Reichert et al. 2001). Conversely to established practice in the 1950s, Wiebe's challenge was a profound one: It was about a conscious and sustained effort to educate and influence the public on what can be broadly described as the greater good of society. It took time for the shift to occur in marketing practice beyond the use of advertising media.

Treating social causes by a form of marketing mix took time. When aiming to address societal matters as marketers would treat products and services, early practitioners (and theorists alike) had to create a new set of rules and methods fit for utilization by rethinking and adapting those adopted from commerce. Early examples of effective marketing practice for social betterment can be found in the 1960s, with Richard K Manoff as

²With the likely approval of contemporaneous governments, Google and other technology giants had taken upon themselves the role of spreading awareness of health matters as well as campaigning in favor of good safety practice at the time of the global COVID-19 pandemic likely to leave a lasting socioeconomic legacy.

³The term "social marketing," hereinafter; i.e., presented in lowercase.

⁴Included among the insights concerning persuasion in Wiebe's ground-breaking 1951 text: Public engagement, PR aspects of sociopolitical roots of Wiebe's treatise draw readers' attentions to the 1943 bond selling campaigns for social good, i.e., winning the war against fascism (1951: 682–3).

the most prominent pioneer. This was followed by theoretical treatises that had fully articulated the term in the early 1970s, where Kotler led the way.

Highlighting the need for further recognition of Wiebe's unprecedented paper is mainly due to its critical, judicious significance best observed in meaningful retrospect. What seems unique about Wiebe's seminal text is how advanced its thinking was for its time. The complex understanding of *advertising (and implicitly, marketing) as social mechanism* truly comes to the fore decades later. The fullness of Wiebe's proposition is manifest in the current age of multiplicity of media forms, devices, channels, formats, messages, and of the breadth and depth of health-related and environmental discourses, variety of suppliers, and global audiences.

Moreover, there are several other aspects of this seminal work that have attracted the attention of practitioners and theorists alike over the decades. Further insightful illustrations include the counterpoint of social good and *the merchandising of commodities*, whereby "cultural objectives cannot be purchased at your nearest drug or department store" (Wiebe 1951: 680) pointing out with great accuracy that *retail outlet acts as a social mechanism that facilitates a desired behavior*. Once more: Many years on, unceasing development of critical management studies continues to address such inherent complexities at the level of definition.

A remarkably persuasive work by Andreassen⁵ (1994: 108) lays the foundation to its entire discussion at *the level of definition* ("Why Definitions Matter") on the level of definition *as prime cause*; it is worth addressing a few more remarkable thoughts from 1951. *Minimum expenditure of energy on the part of audiences in advertising* (and by extension, marketing) was frequently considered by esteemed authors in this field. Especially so as applies to a more sophisticated

and advanced, abstract aspect and notion of "Price" of the social marketing mix.⁶

As it took time for the work of social marketing to build momentum, major leaps occurred in late 1960s practice and early 1970s theory as mentioned above. Projects by the USAID in the 1970s across Africa, Asia, and South America, cover a wide range of subjects including agriculture, family planning, nutrition, oral rehydration products. Since the late 1980s, significant new involvement of commercial and non-governmental actors took place in fields beyond those established⁷ (e.g., Freimuth et al. 1988; Ling et al. 1992; Walsh et al. 1993).

Following comparatively nascent and experimental developments, social marketing had become a truly global practice, and particularly prominent in global health improvement strategies especially aimed at developing countries, as a number of treatises from across the academic and practice spectrums show this to be the case (e.g., Claeysens 2013; Firestone et al. 2017; Gebremariam 2005). Areas relating to developed countries tend to focus on alcohol (Kubacki et al. 2015), smoking, and drugs (more detail in section below). Gender-based violence (in the West) is also covered in theory and practice (e.g., Paluck et al. 2010). Global studies of the reach and effectiveness of social marketing for health purposes tend to include SOCMOB (social mobilization, e.g., in Ling et al. 1992) and FOAM (free open access medical education, e.g., in Burkholder et al. 2018).

Critiques of social marketing relate to ethical convolution, effectiveness and targeting, impact (sometimes with undesired outcomes), measurability, and wholesale utility of some approaches, among others. Also, as indicated at the very level of definition above, there are intrinsic contradictions between the constituent respective fields on which social marketing is based. Those internal tensions between constituent fields include their

⁵This text was addressed more than once; a notable example is a somewhat dialogic response approach by Dann (2007) who explores the connotations of the discipline's value neutrality vs. ethics and dissects the self-definitions as viewed by practitioners.

⁶An abstract yet impactful notion of price as effort, which also plays such a key role in early twenty-first century "seamless engagement" practices in the more recently established field of interactive digital marketing

⁷Counterpointing the involvement of Kellogg with the subheading of this text as "prevention for profit."

respective generic aims and necessities, and the requirement for abstract approaches to strategic framing complicates matters further; such strategic framing, being characterized by continuous long-term programs with very specific and concrete outcomes in mind.

Counterpoints: Practice vs. Theory; Marketing vs. Public Health; Inherent Ethics vs. Generic Tools

Practitioners and authors alike tend to address the tension between theory and practice, also, the intrinsic gaps between social good and tools employed, adopted, and adapted from commercial contexts (e.g., Robinson 2009/2011; Rothschild 1979, among many others). Kotler and Levy (1971) set the tone for much of social marketing programs and approaches to evolve over the decades by defining *demarketing*. This is particularly visible in healthy nutrition campaigns and anti-smoking (de)marketing prominent in developed Western economies. Thus, while Gallopel-Morvan et al. (2011) applaud the effectiveness of visual warnings on tobacco packaging, Hastings et al. (2004) advise caution⁸ concerning fear-focused campaigns: while those targeted seem largely unaffected due to confounding factors such as education, fear-oriented marketing in authors' view appears to raise anxiety levels among those audiences already more conscious of health concerns. Targeting and segmentation are well-covered in some critical work. For example, in Newton et al. (2013), the intersection of ethics and segmentation was explored at length utilizing different ethical frameworks of *just health care (TJHC)* and *integrative social contracts theory (ISCT)*, belonging to distinctive

fields constituent and present within social (health) marketing.

There are reasons why so much of this entry demands focus on health. Other socially compelling fields such as (ethical) tourism (Truong and Hall 2013), (information) security sectors (Ashenden and Lawrence 2013), or racism (Madill and Abele 2007) tend to suggest that still much needs to be done to successfully adopt social marketing practice to the benefit of these multifaceted and momentous fields of behavioral practice closely intersecting with social life and the economy. Environmental sustainability matters share many features with health issues addressed in social marketing, including the fact that this field too had enjoyed relative success as compared to the above (e.g., Lefebvre 2013; Maibach 1993; McKenzie-Mohr 2000).

The subject of delinquency (briefly referred to by Wiebe in 1951) does not seem to figure visibly in social marketing literature; there are examples of tackling youth violence through social marketing (e.g., Quinn et al. 2007). Public information programs seem more prominent in those areas of life, and it is open to discussion what sort of long-term societal investment combined with coherent state strategies need to be adopted for social marketing programs in those delicate subjects. The one aspect of social marketing that does relate to all of the above is also well-reported in its use for health purposes: that of education, namely, *educating* the targeted groups, contingently named *audiences* and/or *consumers* in much of the literature (terminological examples are plentiful; e.g. Gregson et al. 2001). The concept of "education (programs)" plays a considerable role in social marketing practice.

The built-in incongruences of public health (education) and marketing become apparent at more fundamental levels: those of health education, social science, and business practice, respectively. Economic imperatives, various interests involved, and the ongoing fluidity of the notion of "public" may all come to the fore. However, the different logics of such disparate disciplines involved in social marketing appear recurrent from the outset. In addition, the

⁸Other critical texts point out that the drugs prevention programs (in NE England) had failed to attain professed goals, requesting a rethink for the "intervention mentality" (Hastings et al., 2002).

definition of “common good” is also a fundamental principle to be considered.⁹

Quoting Wiebe for insight “The social scientist often disavows the achievement of a specified behaviour as an objective” (1951: 679) indicates the inherent discursive rift between the pragmatic core of marketing practice and the critical insight sought by social sciences. This is not only a matter of applicability alone. Hence, inherent variances between the ideations of respective constituent disciplines may be traced along the historical and practical developments of the interaction of components in an intrinsically hybrid, convergent, conjoined discipline such as social marketing.¹⁰ Indeed, Lacznia et al. (1979) cite marketeers’ concerns about being perceived by the public¹¹ as “neopropagandists.” It appears such matters are largely resolved not least as the field of social marketing had become a profession and a sector in its own right. Some critics of social marketing argued in favor of balance with media advocacy (Wallack 1990: 1991), a high-end publicity and media strategy affecting the way corporate media operate, with the support of state-sanctioned decision-makers. The practice of social marketing is set to develop further, and as the interdependent globalized world enters a new set of health challenges epitomized by the COVID pandemic and emerging related threats, the global, personalized, and highly targeted reach of social

marketing is likely to spread further and deeper, utilizing digital communications, devices, and new generations of social media.¹²

Potential Developments

Sustained impact of social marketing campaigns is one of the main critical points highlighted by experts across the board. Long-term nature of programs, strategic design, accuracy of targeting and research, quality of communications, engaging educational aspects, non-judgmental approaches, and understanding of target community imperatives, habits, traditions and belief systems, feedback loops, and post-campaign data collection and analysis – all figure as key components of effective social marketing programs. The authors across the board also agree that there is a need to understand all of those and many more as sources of potential pitfalls to be addressed in advance and through the duration of the program implemented in field practice.

One of the novel features of social marketing that had emerged during the COVID outbreak is the need to utilize digital communications, social media, and information campaigns in uniquely targeted ways (Chen et al. 2020; Semple & Cherrie 2020). Western responses to the pandemic do include those and other tools. Unprecedented moves by technology giants – especially the world’s leading search engine – may usher a new era in social marketing as ICT firms adopt a new social role (Google 2020; Lee 2020).

Summary

Social marketing has developed significantly since it was first defined in the 1950s. Arguably, some forms of social marketing existed before the term was coined and the practice identified as a distinct field of activity. The engagement of

⁹ *Common good and social betterment* can be seen to have a fundamentally utilitarian ring to them. Such definitions in modern society may not possess deontological value. Thus, utilitarianism may not be pronounced as such in social marketing – though there are authors that indicate that quite clearly. Moreover, the shift from the common good defined as welfare (Hayek 1978) had occurred during the infancy of social marketing. Hence, it is not the commissioned but the logic of commissioning that may require more scrutiny.

¹⁰ Social marketing is by no means an exception; Bloch (2012) provides an authoritative exploration of similar ontological chasms between natural and social sciences in anthropology.

¹¹ Given the continued contentious status of the neighboring area of public information campaigns into the twenty-first century, such concerns do not appear entirely unfounded (e.g., Brownsell 2009; Seymour 2013). See also Weiss & Tschirhart (1994) for policy-led ‘apologesis’ of such practice.

¹² It is not without irony that *social marketing* may in earnest adopt the tools of *social media*, frequently confused by an uninformed reader.

business tools and methods for the common good is not without controversy; some authors suggest that it may be counterproductive at times; others point at the increased marketization and commercialization of its methods and goals. Nonetheless, all agree that it is relevant, important, and impactful. The practice of social marketing is not only to stay: it is ever evolving and becoming more sophisticated, utilizing a number of tools and methods including the transformative and impactful interactive media, this especially in the wake of the COVID pandemic.

Social Marketing, Development Education, and Corporate Social Responsibility: The Common Grounds Sustainability

Chahid E. Fourali
London Metropolitan University, London, UK

Synonyms

Corporate social responsibility (CSR); Development education (DE); Social marketing (SM)

Definition

Although the concepts covered in this section are relatively new with clear meaning, development education (DE), social marketing (SM), and

corporate social responsibility (CSR) have been at times confused with other terms. Hence, it is perhaps important to remind the reader that development education is not about educational development, and social marketing is not about social media marketing, causal marketing, or even social entrepreneurship marketing. Given that the title refers to three concepts, we will proceed to defining them in turn. First, we will focus on SM.

SM is a recent field that appears to have crystalized over the last 40 years or so. It initially appeared as a sister discipline to marketing when some marketers noted that it would make sense to apply the powerful techniques of marketing to address social issues. A definition that was suggested by an international committee of marketers defined the purpose of marketing as follows: *“To apply marketing alongside other concepts and techniques in order to influence individuals, organizations, policy makers, and decision makers to adopt and sustain behaviour which improves people’s lives”* (Fourali 2009, p. 21). Soon after a consensus definition endorsed by the International Social Marketing Association, the European Social Marketing Association and the Australian Association of Social Marketing among others was created. It was designed to define more clearly the key dimensions of SM, including purpose, principles, and procedure as follows:

Social Marketing seeks to develop and integrate marketing concepts with other approaches to influence behaviours that benefit individuals and communities for the greater social good.

Social Marketing practice is guided by ethical principles. It seeks to integrate research, best practice, theory, audience and partnership insight, to inform the delivery of competition sensitive and segmented social change programmes that are effective, efficient, equitable and sustainable. (French and Russell-Bennett 2015, p. 140)

According to the above definitions, SM is to be differentiated not only from commercial marketing but also from social responsibility initiatives. The reason for the latter is that while some CSR initiatives may be undertaken to enhance a company’s brand, SM’s primary purpose is social and does not seek potential commercial gains from its projects.

Regarding DE, it is seen as education for social action and improvement. It aims to address inequalities (local and global) through critical analysis of social issues and the promotion of social change through education. It particularly targets neoliberal views of competitive individualism and promotes a more inclusive humanitarian perspective.

For CSR, it has been defined by the World Business Council for Sustainable Development (WBCSD) as:

the continuing commitment by business to behave ethically and contribute to economic development while improving the quality of life of the workforce and their families as well as of the local community and society at large. (Watts and Holme 1998, p. 3)

CSR position appears to encourage businesses to assume their responsibilities towards social and environmental issues since these businesses depend on the support from these two dimensions, according to the noblesse oblige principle.

The above three areas (SM, DE and CSR) are very similar in their thrust for addressing social issues and should be contrasted to identify opportunities for mutual learning.

Introduction

There are several disciplines that have been designed to help address social disadvantages and environmental irresponsibilities. CSR, DE, and SM are three of them. These three disciplines should be contrasted in turn to identify opportunities for mutual learning. Although the above three definitions appear to show broad similarities in purpose, it would be still useful to look at them more closely and decide how much similarities and differences can be observed at: philosophical, procedural, and effectiveness of each approach. In turn, the observed similarities and differences may highlight certain strengths and weaknesses that may represent opportunities for improvements for each of the three areas (Fourali 2018).

Philosophically, a number of CSR practitioners announced that there does not seem to be a clear philosophical tradition that underpins the discipline. One might argue that this may not apply to DE or SM although a more worked out system of ethics

could be developed that clarify to all the interpinning principles and addressing objections from various perspectives. SM programs routinely argue that their aims are both individual and social good (which, presumably, are also the aims of DE and CSR) and advise practitioners to refer to both deontological (rights and duties) and utilitarian principles (size of beneficiaries) which are not necessarily at odds with each other. Accordingly, one might consider the golden rule (treat others as you would wish to be treated in the same situation) a basic reference for all three disciplines, given its worldwide acceptability in most cultures. Obviously, there are always critics of any rule, but once we have a broadly acceptable ethical basis, we could always develop its interpretation and application in various contexts to maximize benefits. For example, a commonly shared perspective by the three disciplines appears to be their caution against excesses of ideologies, especially neoliberalism. Such warning was already there in education (the eldest of the three disciplines) in the eighteenth century when an enlightened approach to education was strongly advocated. Having said that, it is clear that the current approach of CSR addresses any excesses by encouraging businesses to take into considerations all stakeholders and not just traditional ones such as shareholders or clients. They would advocate for the inclusion of employees, suppliers, customers, local communities, etc.

Procedurally, one might consider both strategic and methodological dimensions. If we consider critical methodologies, one might argue that DE has a tradition of critical discursive approaches which seem to be far ahead of SM and CSR. This may simply reflect the longer history and, therefore, maturity of education in general and DE in particular, compared to the relatively new fields of CSR and SM. DE's qualitative research methodology is supported by several approaches including postpositivists, constructivists, critical theory, humanists, postmodernists, etc. However, DE does not seem to have yet developed (or at least adopted) consistent strategic approaches of implementing programs. Despite the occurrence of some models, they seem to appear to be too broad in perspective to accurately and systematically implement. This is

no surprise as some DE practitioners have already pointed at this weakness.

Critically, although SM and CSR appear to have a less mature critical research tradition, they seem to compensate for this weakness by the practical procedures they adopt in analyzing situations and implementing strategic changes. This is due to the fact that both these disciplines have historically been derived (at least partly) from the world of business. For instance, if we consider CSR, we may refer to Carroll's CSR model that systematically identifies various forms of responsibilities (Economic, Legal, Ethical, and Philanthropic), their justification, and interpretation for the company. On the other hand, SM is developing powerful techniques for planning and implementing social marketing programs that may be selected and adjusted to different scenarios (e.g., Fourali's or Kotler's). As an example of a systematic approach to SM, consider Fourali's 11 step model including problem identification, planning/scoping, developing a purpose, situation analysis, targeting beneficiaries, specifying objectives, clarifying the offer to target group, selecting an effective marketing mix, gathering resources, implementation of campaign/program, and monitoring situation. These steps benefit from an armamentarium of tools derived from various disciplines to maximize the effect of the campaign.

Regarding the evaluating the effectiveness of each discipline, both SM and CSR would claim that there is plenty of evidence to demonstrate the effectiveness of their projects. In contrast, DE's evidence appears to be patchy and the jury is still out there about what would constitute an effective way of measuring its effectiveness. Again, a number of DE practitioners argued for the development of measurement strategy tools to gage the impact of the projects. Some argued for the adoption of business models such as Kaplan and Norton's balanced score card.

In the light of the above one might ask "what lessons one may derive from the above analysis?"

Regarding the complaint aired by some educationists about the lack of clear evidence for assessing the impact of projects by DE workers, a number of suggestions have been put forward as to the cause of this weakness. These include: lack of experience with business management tools

that are focused on evidence-based decisions; distrust of ‘business-related tools’ perceived by some educationists as reminiscent of neoliberal ideology; more focus by DE workers in critical, liberatory dimensions of education, and the interpinning structure of disadvantage; branding of educational initiatives as reflecting unique situations and, by definition, are not amenable for generalizability to other situations. However, one might argue that while these arguments may explain some of the reasons behind the lack of work on assessing the impact of DE, they do not justify the situation. Indeed, since DE’s purpose is to help alleviate the human condition through education, it would be very hard to achieve this without systematically evaluating the outcomes of its various projects.

In terms of philosophical development, both CSR and SM can learn from DE since it has a more developed philosophical tradition linked to generations of studies on educational goals and principles that can help create a more equal society.

Methodologically, DE also has a longer tradition of educational research, particularly the use of in-depth qualitative analyses. Again, such advance could benefit both CSR and SM.

Perhaps a third area from which CSR and SM can benefit, and linked to both philosophy and methodology, is the critical traditions that DE has been associated with. Such critical traditions help understand the context or history of certain state of play that should present richer information to help social change projects. In particular DE has a strong tradition of awareness of the effects of education, history, or power on our societies. Current examples of power, such as the triple domination bottom line of media, finance, and political hegemony, are routinely reviewed by educationists.

On the other hand, DE can also learn a lot from CSR and SM work. In particular, both CSR and SM, and especially SM, have demonstrated a rich and integrated eclecticism (i.e., their ability to borrow tools and technics from various disciplines to benefit their programs). Such disciplines included psychology, sociology, marketing,

management, etc. This should come as no surprise since both CSR and SM are traditionally linked to business environments where effectiveness and efficiency are key performance indicators for the success of a program. It is worth noting that adopting business models in CSR or SM is not a blind adoption of neoliberal philosophy. Rather it is an attempt to ensure that practitioners demonstrate the effectiveness of their programs which, in turn, justifies more support and investment in their social initiatives.

Key Issues

There are several initiatives purporting to help with social problems or justice. So far, such issues appear to have worked separately despite the similarity of the ethical aims. Their separation may be due to disciplinary walls rather than similarity of purpose. It is arguable that the realizations of the shared aims (social, environmental, and governance) can be much more helped if these three fields of studies start looking beyond the historical walls (such as education, versus governance versus business issues) and look for common aims and how best to achieve them using similar or combined methodologies.

Future Directions

It is envisaged that the three disciplines of development education, CSR, and SM could start systematically learning from their strength and weaknesses and develop ways of mutual sharing of expertise to help make them more effective. Such learning can be done through improved communications but also through seeking learning from beyond the usual “boundaries” of the disciplines. Accordingly, researchers in the three disciplines should look for breakthroughs as well as effective practices and arguments with a view to adapt them to their respective circumstances. This should not be difficult to undertake because of the natural similarities of their purpose.

It is important through that the rapprochments should avoid nonthought through adoptions that may lead to confusions and inefficiencies. It is of crucial importance that the theoretical underpinning is thoughtfully considered before determining their relevance to each situation. Hence, we advocate a theoretically consistent eclecticism.

There may be several ways practitioners/researchers in these respective fields can start learning and consulting with each other. In this respect, developing multidisciplinary communications and forums are encouraged in as sober a manner as possible without disciplinary partisanship that may prevent the free flow of ideas. Rather the approach should be how can we support our respective audiences and what can we “borrow” from each other’s successful experiences. To do this, it is important to develop transparent tools for assessing effectiveness and efficiencies that can help identify areas of strength and weaknesses rather than spend time in empty debate or presumptions that do not help advance the fields. Ultimately, any advance in such debate would help improve the human condition, which should be a guiding principle.

[Commitment](#); [Corporate social responsibility](#); [Responsibility](#); [Social commitment](#); [Social responsibility](#)

Definition/Description

Social obligations in corporate social responsibility (hereafter CSR) represent the commitment of business entities to proactively engage with stakeholders to address social issues such as protecting human and children's rights, preserving health, addressing poverty and unequal wealth, and preventing corruption or unethical trade and labor practices. It is a commitment to create positive business impacts and distribute them fairly to the company's stakeholders while respecting social customs and expectations. In this context, the term *obligation* could be synonymous with the term *responsibility* (in the corporate sense). The adjective *social* is regularly used in the concept of corporate social responsibility and represents the core value of CSR. It usually covers all environmental, social, and governmental (ESG) aspects and balances them. Modern business organizations, due to their role in society, do have a strong impact on the development of society and

affect them directly through their own activities. There is almost no crucial problem in modern society that can be solved without the direct involvement of the corporate sector. Therefore, corporate social obligations include the sensitivity of a company, its managers, employees, shareholders, and other stakeholders to various issues of social life within a specific society. Social obligations formulated through a specific set of actions are part of the CSR strategy and sustainability of its business model.

Corporate Context of Social Obligations

As society is changing, standards do too. Even before Friedman and Freeman published their work, the social responsibility of business was a topic of discussion among shareholders and different stakeholders. Bowen's (1953) understanding of the social responsibility of businessmen was "the obligation of businessmen to pursue those policies, to make those decisions, or to follow those lines of action that are desirable in terms of the objectives and the values of our society." Barton (2011) wrote that we should rethink *how we view business' value and its role in society*. Managing social obligations may be considered as a matter of making a balance between corporate interests and social objectives. However, such a comparison does not represent a full-scale picture of corporate social obligations since business and social goals are inevitably interconnected. A company is primarily a social organization because it consists of human individuals, the employees. This "human element" makes a company function like a live organism, responding to surrounding impulses. People that make up a company have cultured ethical values, which are usually consistent with generally accepted behaviors. Therefore, social obligations in business are not something that is done and controlled operationally – on the contrary, it is a permanent relationship and responsiveness of a company beyond its economic goals.

The development of a strong corporate society prevailed from the 1970s to 2000 with an exclusive focus on finances and market values.

Corporations made high profits while neglecting the extremely harmful consequences of economic growth, such as environmental damage, corruption, and social injustice. The moral integrity of corporate managers was up for public debate in many cases of child labor, violations of health regulations, or the irretrievable destruction of large amounts of land. Therefore, the public call for strong corporate responsibility was justified. Early discussions of CSR were only about dividing companies into those that "choose" to be responsible or not. Responsibility cannot be a matter of decision-making because no one should choose to act morally one hour and immorally the next. That would be inconsistent and corrupt behavior. Expressing social sensitivity as an option was counterproductive and revealed that the corporate sector did not fully understand the social obligations it has to deal with. Companies that did not comprehend their social obligations did not learn about CSR until consumers became aware of the impact of companies on sustainable development and consumer habitat. Therefore, the discussion of whether a company accepts or denies social obligations is not fruitful because it can jeopardize its very existence. The only sensitivity to these issues was the moral and ethical orientation of the people performing the business actions from the top to the bottom of the organizational hierarchy.

The relevant context of social obligations in CSR represents a valid ratio made of applied legal conduct in alignment with social expectations. The term and context of social obligation is a fundamental component of CSR, but it does not have to be a synonym for responsibility. Although there is no unique definition of CSR, one is constant: They regularly refer to the social obligations of companies. The context of social obligations is found in almost every CSR definition. Kotler and Lee (2005) define CSR broadly as "a commitment to improve (societal) well-being through discretionary business practices and contributions of corporate resources." Wan-Jan (2006) stated that the "lack of a widely agreed definition contributed to misunderstandings and cynicism towards the (CSR) concept itself and argued that hence the need for a working definition." Wan-Jan (2006

Social Obligations (CSR),**Fig. 1** Building strategic social obligations. (Ditlev-Simonsen, 2022)

citing Kitchin, 2002) captured the problem of defining CSR well, stating: “One moment (CSR) seems to mean the engagement of non-governmental organizations (NGOs), the next it is all about charitable donations, and 5 min later it seems to mean the ethical treatment of employees.” Moratis (2016) acknowledges the shift in CSR definition by ISO 26000 “as it propagates an explicit moral perspective on corporate responsibilities towards society.” This shift makes corporate moral responsibility a minimum standard of social obligations rather than something a company can choose to do. Every CSR approach, however different, has a social obligation or responsibility built into its core.

In CSR, the term social obligations refer to concepts such as social issue, social concern, social activity, social impact, social responsibility, social performance, and social risk. Sethi (1979) states that “corporate behavior in response to market forces or legal constraints is defined as a social obligation.” The way employees, managers, and owners of a company perceive a particular social problem is a way they construct the company’s

response to that problem. In this way, companies develop conducts for socially responsible action, such as CSR policies. As seen on Fig. 1 for approach to be strategically sustainable, the initiative needs to come from top management, or at least it should be anchored in top management. CSR is not “add on” for the company but needs to be integrated within structure, culture, and strategy. Explicitly expressing the company’s commitment to sustainability is of crucial importance. After that, managers should first and foremost identify the key areas of social impact and map them, so the management must take account of what they are already doing. After management realizes the current state, they can set concrete goals associated with the areas where the company has a major social impact (Ditlev-Simonsen, 2022). For companies, in general, it is better to be part of the solution than part of the problem. In the study by Kasturi et al., CSR is considered a necessary aspect of corporate culture and should be aligned with organizational behavior (2015, StudyCorgi, 2020). Helping others is a natural response and a socially evolved behavior. It is an

instinct, a particular social behavior (obligation) of any being that perceives when others are at risk or suffering from adverse conditions. Company social obligations can manifest in a variety of responsible behaviors. Carroll (1991) sees several corporate social obligations: as economic, ethical, legal, and philanthropic. Jamali and Mirshak (2007) make a connection between Carroll's multiple perspectives and Windsor (2001) when they say: "From this perspective, economic and legal responsibilities are socially required, ethical responsibility is socially expected, while philanthropy is socially desired." In this statement, the words "required, expected, desired" determine the propriety of activities that a company or its managers should or should not do. This determination makes the corporate context of social obligations about morally correct and socially expected behavior. The next step is to consult with stakeholders to collect feedback on the plan (Fig. 1).

From Stakeholder's Expectations Over Social Obligations to Social Changes

When it comes to social obligations, the following question arises: Is it social responsibility or social obligation? There is a difference between an appropriate response (responsibility) and an obligation. In CSR, there is a constructive relationship between the two. Managers do not have a duty to act morally; morality is a personal sense of righteousness. A company may fulfill an obligation (social, legal, political, or otherwise) through a contract based on law or industry regulation. A company's obligation may be to take positive social or environmental action, but this does not mean that it has developed a moral sense of responsibility. Obligation means acting lawfully, i.e., acting as required by law, public institutions, or valid social guidelines. That is why some perceive CSR as acting beyond legal requirements. In the case of social obligations (CSR), companies develop codes of conduct, policies, and regulations to ensure that they act in a socially acceptable manner. It is not the same intuitive response if a company refers to a social problem only with a PR statement or if the company gets involved in

solving the social problem with other community members.

Stakeholders are crucial for the competitiveness of business organizations, and their relevance is immense and obvious. Therefore, it is very important for a company to clearly identify its social obligations if it wants to achieve CSR or specific sustainability goals. The company must properly identify its social obligations to develop the right policies and procedures to ensure appropriate social impact on a regular basis. Social obligations vary widely from one company to another and depend on the industry and community in which the company operates. Different industries face different types of social obligations. The social obligations of an automobile manufacturer regarding safety of passengers differ significantly from those of a pharmaceutical company and safety of patients. In addition, a car manufacturer will have to deal with safety issues of road users or high greenhouse gas emissions due to large-scale production, while pharmaceutical companies will have to commit and deal with the ethical issue of animal testing as part of their R&D process. These two companies have different stakeholders, and therefore their perception of social obligations is different. Isa (2012) summarizes this stakeholder perception as follows: "CSR means something to everybody, although not always the same thing." How well managers understand stakeholder expectations determines how they perceive the company's social obligations. This is evidenced by Clarkson's (1995) 10-year observational data that confirmed: "(1) corporations manage relationships with stakeholder groups rather than with society as a whole, (2) it is important to distinguish between social issues and stakeholder issues..." This means that social obligations derive from stakeholder needs that companies are trying to meet. Stakeholders contribute extensively to the formulation of CSR policies, through early-stage dialogues balancing the conflicting belief of profitability and social obligations related to social responsibilities dimension (Basavaraj & Sreelakshmi, 2022 citing Lauring & Thomsen, 2008) There is no doubt that business organizations will constantly create different values in a

modern society, but which type of value will have social advantage? The forces of influence of various stakeholders (especially internal ones) are becoming more powerful and can no longer be ignored. Perhaps modern organizations could be described as a network of influences that creates economic value within a specific social context.

The way Frederick et al. (1992) divided a company's stakeholders into primary (internal) and secondary (external) stakeholders indicates the multidimensional nature of social obligations. This makes the list of corporate social obligations quite long and raises the question of what are the basic (narrow) versus broader corporate social obligations. A study of Australian managers by Quazi (2003) found "a significant relationship between the level of education, training status, and religiosity of managers and their perception of CSR." This implies the relationship of managers' perceptions, their patterns of social commitment, and the creation of socially responsible human resource policies. Wartick and Cochran (1985), in presenting the model of corporate social performance, state that the challenges of CSR are

as follows: "economic responsibility, public responsibility, and social responsiveness, it also examines social issues management as a dimension of corporate social performance." All of the above terms contain the adjective "social" because of social differences within stakeholder needs and expectations. The wide variety of stakeholders leads to a wide range of possible social obligations that a company must deal with (Fig. 2).

Additional challenge for companies managing stakeholder expectations is that these expectations change over time. Stakeholder diversity is driven by constant social changes due to market realities, innovations, or global trends. This leads to a changing context for the company's social obligations and the social performance of managers (Fig. 2). By fulfilling their social obligation, business organizations balance between their short- and long-term goals. Barton (2011) wrote that business organizations should fight their myopic way on social reality and revamp incentives and structures to focus their organizations on the long term. Porter and Kramer (2011) state that

Social Obligations (CSR), Fig. 2 Perceiving social obligations and change

business, acting as business and not as charitable donors, can become a powerful force in addressing societal issues. Instead of buying conscience through nonsystematic donations and philanthropy that are not related to the strategy, management should utilize power, resources, knowledge, and talent of business entity to address some of the greatest issues humanity faces today. It is not a one-size-fits-all solution, but as seen on Figs. 1 and 2 management should carefully pick social obligations that are related to its business model.

Relevance of a certain social change can significantly affect the corporate perception of social obligations. Nickels et al. (2008) point out the relevance of social change, explaining, “Far smaller and far slower social changes in earlier periods triggered civil wars, rebellions, and violent intellectual and spiritual crises. The extreme social transformations of this (twentieth) century have caused hardly any stir.” Contemporary social changes affect a wide range of business aspects, from individual development (Stewart & Healy, 1989) to the development of business opportunities (Bergh et al., 2011). Any societal change can create new stakeholder expectations that may require a new type of response from the company. At a certain sociological moment, companies need to develop strategic sense of stakeholder needs. Such a sense cannot be created by legal, economic, or other mandatory instructions. Because society is in a constant state of change, the corporate content of social obligations is also constantly changing. This emphasizes the importance of constant coordination between stakeholders and the company. Such coordination can ensure that a company regularly discusses common interests and social values with the community. But plan is nothing without execution.

The implementation procedure ensures that desired results are achieved and is the underpinning for implementing change. CSR goals are not always part of job description, so the most effective and efficient way to include them is to quantify them and integrate them as a part of progress evaluation and follow-ups. Another efficient and effective way is to include them as a part of compensation plan through CSR bonuses, where

CSR goals become an integral part of employee's working performance. Here the amount of paid bonuses directly correlates on both, employee's and organizational performance that can be tracked and measured. Employees will be more productive if they can demonstrate progress, maintain records of their work, reach specific CSR goals, and receive encouraging variable compensation (bonus). On the other hand, it will help the organization to accomplish its sustainability goals.

At the end, the company should present on its CSR objectives, not only because this type of reporting will soon become mandatory and there are already ESG compliance regulations in place, such as EU taxonomy **and the EU corporate sustainability reporting directive, but also because it is a healthy managerial practice and makes a foundation for a long-lived, resilient business model. At the moment, EU law requires certain large companies to disclose information on the way they operate and manage social and environmental challenges, but trend is clear, and soon every organization will have to disclose some kind of report on ESG objectives.** Management should regularly communicate the fulfillment of their social obligations to stakeholders hoping to create additional value for both. Often companies realize that they are doing a lot in the pursuit of sustainability – they just do not call it sustainability or corporate responsibility (Ditlev-Simonsen, 2022). The most appropriate communication of this type is CSR disclosures, commonly known as CSR reporting, nonfinancial reporting, ESG reporting, or integrated reporting. Companies that have CSR programs may use CSR reports to demonstrate their dedication to generating social value and safeguarding social interests. It is a two-way communication between stakeholders and companies about expected, implemented, and achieved social obligations. This kind of report makes it possible to assess a company's social commitment as well as the degree of openness toward society.

ESG-related reports provide a consistent means to track, evaluate, and analyze CSR performance and overall health of the business organization while identifying crucial areas for impact

improvement, compiling an organizational knowledge base and opportunity for future growth. It also keeps management and stakeholders advised on what is happening in organization. By definition, reporting is a backward-looking process, but it allows also a forward-looking component that gives management opportunity to share reached and future CSR goals within different time frames (Ditlev-Simonsen, 2022). It is vital to break big objectives down into smaller chunks because many CSR ambitions require years to be achieved. Becoming zero-impact continent or carbon-neutral organization will take decades; therefore, a comprehensive strategy is crucial. Holistic approach means to have clear, tangible, and measurable connections between operational and strategic CSR plan, ESG reporting, performance management, and rewarding policies. All usually fragmented and scattered elements need to work in harmony and be coherent if organization wants to be truly competitive and achieve balance between long- and short-term objectives.

Manager's Perspective on Company's Social Obligations

What do companies strive for when they fulfill social obligations? Is it just about the moral satisfaction of the managers, the fulfillment that they have done something good for society, satisfied the stakeholders, and behaved appropriately? For a company, fulfilling a social obligation means participating in the process of creating and managing social value. Social value accounts for nearly two-thirds of the company's Triple Bottom Line (TBL, Elkington, 1998). Businesses have unique organizational capabilities to create, accumulate, process, and disseminate different types of social value. Entrepreneurship is a creative process of creating new economic and social values. When companies process social value, they must do so in an appropriate way – and that is their core social obligation.

Social obligations combine the acceptance of ethical standards and morally bound actions of corporate persons. Ethical and moral

underpinnings represent a genuine commitment by the company to determine what is and is not socially acceptable. A manager's moral sense is instilled in him as a person through his cultural upbringing and education, which means that social obligations are a matter of deeply held personal values. What a person becomes in their career cannot be known in advance, but the person's developed moral values should enable constantly positive, socially safe actions and prevent negative consequences. What happens if a businessperson does face a situation where they have conflicting duties, responsibilities, and/or obligations or they cannot satisfy all at the same time? In that case, one thing is for sure, they must make a decision, and Becker (2019) suggests they need to ethically reflect on an organizational set of values, norms, and principles and make a decision about their hierarchical order: What type of social obligation has strategic priority and overrides others in such a conflict?

There are numerous social processes that are very complex and in which companies have an important stake. The social interdependencies reflect in business social impact. The size of the company may play a role in these relationships. Due to the strong social impact of companies, Lazzarini (2018) emphasizes the importance of implementing social impact measurement practices in companies, as they “can help organizations blend social and economic goals.”

Through their size and global influence, multinational corporations (MNCs) are able to create and process more social value. This has been discussed in the context of the “Bottom of the Pyramid” model (BOP), in which MNCs are seen as an opportunity to improve the socioeconomic potential of two-thirds of the poorest people in global society. Because MNCs accumulate and disseminate large financial and nonfinancial assets, it was assumed that they could also improve social value through BOP strategies. Sinkovics et al. (2014) attempt to convey the understanding and limitations of BOP business models designed to simultaneously create commercial and social value. They emphasize that “what qualifies as social value in one country context may differ greatly in another country

context due to differences in the economic, political, and institutional environment. Therefore, comparisons between the social value created by companies originating from developed and developing countries need to consider the different manifestations and shades of social value.” This approach has been criticized for the contradictory and even negative impacts of MNCs in third world countries. Moreover, this approach has unfairly neglected the social potential of small and medium enterprises (SMEs), especially knowing that SMEs make the “backbone” of national economies due to their number, the highest percentage of employees, and by created and exported value.

In modern markets and in modern societies, there is a constant alignment of economic and social values. Awareness of harmful market trends in relation to social values has reached a point. Under these circumstances, social entrepreneurship has engaged as a nonprofit model to preserve and stop the depletion of social capital. Social entrepreneurs are committed to increasing social value across a range of sectors including activism, elder care, poverty alleviation, biodiversity conservation, sustainable and green agriculture, and health improvement. In terms of creating economic and social value, Acs et al. (2013) argue, “To think of social entrepreneurship as separate from commercial entrepreneurship may not be useful.” They explain that “economic value can be treated as reflecting social value, depending on its context and effect.” For this reason, social entrepreneurship is based on striking a balance between social, environmental, and economic business goals. Social value is inherent in each of the above, according to Auerswald (2009), when he states that “entrepreneurs of various types create both private and social value.” Value creation is a general obligation of any business, while social value has many variations.

Summary

This entry explains the CSR context of social obligations. Social obligations in the modern business world offer companies the opportunity

to add social value to their business. This allows companies to add sustainable social elements to their economic value creation. A company uses different types of social capital (people, natural resources, and infrastructure) to operate and therefore has an obligation to act in a socially appropriate way in this engagement. This entry highlights how social changes affect the way companies perceive their social obligations. Businesses should meet each social obligation equally, while also considering the problem of conflicting social obligations. This conflict can occur when the interests of one stakeholder of the company differ significantly from those of another stakeholder. Social obligations can be determined and fulfilled only if the interests of the stakeholders and those of the company are aligned. In this way, the company can identify the relevant social values to which it must adhere. The biggest CSR challenge regarding to social obligations is the changing nature of social values and their connection with the elements of the long-term sustainability of the business model.

Introduction

While for many years there was confusion about both the subject and the object of social responsibility and even though actual literature is still claiming that there is no “universal understanding of (Corporate) Social Responsibility” (Scherer and Patzer 2011, p. 321; Gogoll and Wenke 2017, p. 183), the concept has been clearly and globally consensually defined some years ago in the first international standard of Social Responsibility: ISO 26000: 2010 (ISO 26000 2010).

The outcome of this standard owns a high degree of relevance and legitimacy because of its consensual development process within one of the largest multi-stakeholder processes in the history of ISO standards (Mueckenberger and

Jastram 2010; Mena and Palazzo 2012; Hahn and Weidtmann 2012). In addition to company representatives from industry in both developing and emerging countries, government and trade union representatives were present, alongside consumers, nongovernmental organizations, and people from SSRO (service, support, research, and others). During a period of 6 years (2005 to 2010), they discussed the form and content of the new standard. In total, experts and observers from 99 countries as well as from 42 private and public sector organizations directly participated in the global development process (Kleinfeld 2011, p. 11; Kleinfeld and Martens 2014, p. 6).

ISO 26000 describes social responsibility in the context of the whole organization, providing guidance and concrete recommendations in order to identify and to take their (specific) responsibilities toward society for organizations of any legal form. The concept of (C)SR promoted by this international standard encompasses a wide range of aspects and, thus, contradicts the hitherto widely held view that it is only concerned with environmental aspects, sponsorship, or pure altruism and philanthropy (see COM(2001) 366 (2001), Green Paper).

Instead, in today’s understanding, SR is perceived as a crosscutting task that runs through all divisions of the company based on corporate policy and corporate governance. Good and credible (C)SR which focuses on an organization’s core business ultimately contributes to its sustainable success and secures its future. (C)SR can be a competitive advantage and a quality feature if properly understood and credibly practiced (Kleinfeld and Kettler 2011).

The History

For a long time, different answers have been given to the question what social responsibility is or should be.

The most provocative understanding seemed to be held by Milton Friedman who in his famous article in the New York Times Magazine from 1970 stated “The Social Responsibility of

Business is to increase its profits” (Friedman 1970). Being a strong advocate of economic liberalism and of shareholder value, he argued that social objectives should be primarily followed by politics since business people, for not having been democratically elected, were neither authorized nor capable of taking over the role of political actors and governments. And, by mixing up the division of functions between business and politics, the basis of a free society could be significantly endangered. Both arguments are rather plausible. Questionable from today’s understanding, however, are the underlying assumptions of this position. This is mainly true for Friedman’s definition of the subject as well as of the object of social responsibility. Regarding the former, he says: “Only people can have responsibilities” (Friedman 1970). Social responsibility of business, thus, means the social responsibility of individuals who manage it. According to the classical position of the principal-agent theory, however, corporate executives are agents of stockholders and owners, so their primary responsibility is toward them and their – assumingly – merely capitalistic interests. Even more outdated is his idea about the object of SR. Following the rationale of his article, acting socially responsible means spending someone else’s money for a general social interest. This is corresponding to only one minor aspect of the definition of SR developed, e.g., some years later by Archie B. Carroll: to the dimension of philanthropy which, according to Carroll and contemporary approaches of (C)SR, is neither an economic or legal duty nor may it be legitimately expected from business by society but refers to something which can only be “desired” (Carroll 1991). Besides, Carroll and other business ethicists of the 1980s and the 1990s ascribed economic, legal, and ethical responsibilities to the corporation as such which was reflected by the use of the term corporate social responsibility (CSR).

However, until today, especially in business practice, it is still widespread to understand (C)SR as (purely voluntary) social engagement (Schrader 2011, p. 303), whereas even Friedman had a broader understanding as a look to the full quote in his article shows:

That responsibility (...) generally will be to make as much money as possible while conforming to the basic rules of the society, both those embodied in law and those embodied in ethical custom. (Friedman 1970)

In Europe, one cause for the narrow understanding of SR can be found in the first definition published by the European Commission in 2001. On the basis of the work of the European Business Network for Social Cohesion, initiated by the European Commission in 1996 (renamed in “CSR-Europe” in 2000), the so-called Green Paper of the EU was developed (title: “Promoting a European framework for Corporate Social Responsibility,” COM(2001) 366 (2001)). With its definition, the Green Paper for the first time established a common understanding of CSR in Europe:

Corporate Social Responsibility (CSR) is a fundamental concept designed to help companies with the voluntary integration of social and ecological concerns into their corporate activities and their relationships with stakeholders. (COM(2001) 366 (2001), p. 7)

Following the Green Paper definition, CSR focuses on the following aspects: voluntary corporate activities in the field of social and environmental responsibility, involving relevant stakeholders.

In the year of the publication of the Green Paper, the demand for an international standard in the area of (C)SR was raised by international consumer organizations and shortly afterward an official request sent to ISO. Almost 10 years passed from the idea to the publication of the final standard ISO 26000 (at the end of 2010): Not only the content of but also the need for this standard was controversially debated before and during its development process. And until the final vote it was not certain whether the majority required for the adoption of the standard would be found.

Another reason for the long duration of the standard development was of course the complexity of both the topic and the special process design. As described above, representatives and experts from six stakeholder categories per country – namely, industry, labor, government,

academia, consumer, and NGOs – from almost 100 countries, organized in national committees and in one international working group (WG SR), were involved in the development process. A balanced relationship between participants from developed, emerging, and developing countries was ensured and actively promoted (Kleinfeld 2011, Vitt et al. 2011, pp. 6, 45–48).

As a result, ISO 26000 offers a comprehensive guide that, although not (yet) approved for certification on an international level, provides concrete recommendations for the systematic recognition, determination, implementation, and communication of an organization's social responsibility. Unlike any other initiatives in the area of CSR until then, it addresses all kinds of organizations, regardless of their ownership structure, legal form, size, and location. Finally, its definition of social responsibility and the definitions of several key terms closely related to SR have been developed and were adopted based on international consensus.

The First Globally Acceptable Definition of SR

ISO 26000 defines social responsibility as the:

responsibility of an organization (2.12) for the impacts (2.9) of its decisions and activities on society and the environment (2.6), through transparent and ethical behaviour (2.7) that

- *contributes to sustainable development (2.23), including health and the welfare of society;*
 - *takes into account the expectations of stakeholders (2.20);*
 - *is in compliance with applicable law and consistent with international norms of behaviour (2.11); and*
 - *is integrated throughout the organization (2.12) and practised in its relationships.*
- (ISO 26000:2010, p. 3)

With this definition of social responsibility, ISO 26000 clearly distinguishes itself from what was understood in common corporate practice by CSR until 2010 (Kleinfeld 2011, pp. 5–7).

As the main object of an organization's responsibility, it highlights the consequences and impacts of corporate and organizational decisions and activities, respectively. The term "social" in this definition of social responsibility refers to the third dimension, apart from the subject and the object of responsibility, which is the authority or instance – here the society and the environment including their health and welfare – answering the question to *whom* the organization is responsible.

In order to identify and to take their specific responsibility, organizations should engage with their stakeholders, firstly by getting to know their interests and expectations, secondly by evaluating them as legitimate or not, and finally by involving relevant stakeholders in the form of a (critical) dialogue within the corporate decision-making processes.

In line with Friedman's and Carroll's understanding of social responsibility, ISO 26000 explicitly includes legal compliance and ethically acceptable behavior into its definition, thus indicating that SR cannot be reduced to philanthropy or a purely voluntary commitment toward society. By referring to "international norms of behavior" as well, compliance in this context is not limited to applicable law but includes the so-called soft law in the form of internationally agreed conventions, guidelines, and other norms, thereby going beyond classical compliance approaches.

Moreover – and this is also an expression of an extended conception of CSR in the light of current practice – the fulfillment of social responsibility according to ISO 26000 requires a holistic implementation approach, which should not only be realized in a formal-structural but in an informal-cultural way at the same time. Responsibility toward society is a crosscutting issue, which presupposes a certain behavior on the part of both the individual actor and the organization as a whole. The related topics and fields of action are not isolated from each other and, therefore, can be considered and treated effectively only in an integrated manner. Responsible decision-making and behavior should become an attitude deeply rooted in the organizational culture and lived throughout the organization including in its

internal and external relationships (Martens and Kleinfeld 2018, pp. 23–24).

According to ISO's definition of SR, by taking this responsibility, organizations can make a key contribution to sustainable development, including health and the welfare of society worldwide. Through a comprehensive socially responsible use of resources (sustainability management), they simultaneously ensure sustainability of their own value creation. Finally, the standard gives recommendations on how to manage organizations sustainably. The primary objective is to promote sustainable development of society through an organization's own decisions and activities and to influence or help other organizations to do the same according to their capacity.

On a European level, as a result of the Lisbon Summit agenda, the revision of the OECD Guidelines at the beginning of 2011, against the background of the financial and economic crisis and, in particular, as a result of the introduction of ISO 26000, the European Commission finally reviewed its understanding of CSR, which is valid until today, according to which CSR is:

... the responsibility of enterprises for their impacts on society. [...] To fully meet their corporate social responsibility, enterprises should have in place a process to integrate social, environmental, ethical, human rights and consumer concerns into their business operations and core strategy in close collaboration with their stakeholders, [...]. (COM (2011) 681 final (2011), p. 6)

Critique

Criticism of ISO 26000, however, should not be ignored. Obviously, the multi-stakeholder process also revealed weaknesses. Because of financial deficits, especially on the part of the NGOs, broad participation of all stakeholders at each international meeting (i.e., during the eight working group plenary sessions between 2005 and 2010) was not possible. Therefore, imbalances (or “asymmetry”) in the influence of individual stakeholder groups could not be completely ruled out.

A frequently mentioned critique is the “indetermination of the ISO 26000's demands.” This

criticism can be countered by referencing the international nature of the target group and the intended universal applicability of the norm, which was not planned to contain “requirements” and guidelines, respectively, since it was solely designed to be a guidance document (Kleinfeld et al. 2019, pp. 8–10).

Apart from this, the standard seeks to provide guidance to all kinds of organizations, regardless of their nature and size, and therefore must reflect the diverse contexts of organizations.

Perhaps the main criticism of ISO 26000 is its high degree of complexity and sheer size. But these traits, at the same time, are its major advantage: the cooperation of the emerging and developing nations has ensured a broad, full-scale consideration of the SR-related issues, thus engendering the standard's universality. On the other hand, a document with implications of such a scale cannot provide detailed recommendations for individual target groups but must remain general when describing fields of action. The task to apply the norm with a view to specific needs is therefore left to the potential user organizations themselves (Kleinfeld et al., 2019, pp. 8–10).

Against this background, one of the first and most important exercises according to ISO 26000 is the identification and description of fields of action (issues) of social responsibility relevant to one's own organization as well as the determination of a company's sphere of influence. The standard itself provides references and orientation and, in some places, addresses the specific requirements of potential user groups. For example, it contains explicit statements on benefits and application for small- and medium-sized organizations (ISO 26000:2010, p. 8) as well as recommendations on how government organizations can orient themselves to the norm, without wanting to replace their special role as a state actor (ISO 26000:2010, p. 9).

Major Accomplishments/Contributions

In a country-by-country comparison, it can be seen that there are different views on what has

been meant by (C)SR (Matten and Moon 2008). Only clear definitions of the term, which have been developed consensually in a global understanding process, would remove ambiguities. This is precisely what the global multi-stakeholder process that led to ISO 26000 was aiming for and in the end could achieve.

Apart from that, the definition and the concept of social responsibility provided by this standard sends a clear signal not only for the necessity but also for the feasibility of ethical orientation in a global economy. Its greatest achievement is to offer for the first time a holistic, integrative, and coherent approach to dealing with ethically relevant topics for businesses and any other kind of organization of the twenty-first century.

Summary

According to ISO 26000 “SR” is the “Social Responsibility” of all types of organisations for their impacts on society and environment (via corporate and organizational decisions and activities) regardless of their size, type of ownership, location and legal form. It comprises a wide range of aspects and emphasises the dialogue with stakeholders (ISO 26000 2010, p. 3).

Definition

The risk is defined as the possibility that events will occur and affect the achievement of strategy and business objectives.

To mitigate risk, companies have to develop risk management systems. Risk management systems fundamentally aim to address uncertainty in the market place. Their primary goal is to create controls and countermeasures that minimize or eliminate the disruption, loss, or damage to business operations and shorten the recovery time from an unwanted event and, thereby, reducing its impact on business.

Nowadays, the results of the greater interdependencies and hidden vulnerabilities that businesses have to face are an increased number of uncertainties in corporate decision-making. Current network-based operating models highlight the growing importance of the extended enterprise by establishing greater connectivity among and between stakeholders across the globe. This connectivity has also created entirely new stakeholders and requires innovative form of risk management.

These changes in the operating model have led to a significant shift in market power – not just customers and traditional investors but also toward stakeholders, such as communities, employees, regulators, politicians, suppliers, media, etc. As a result of this shift in market power, social risk is a rising area of concern for companies.

Social risk arises when firm's behavior or the action of others in its operating environment creates vulnerabilities. In the case of social risk, stakeholders may identify those vulnerabilities and apply pressure on the corporation for behavioral changes. As the ability to listen to corporate stakeholders' perspectives on social issues becomes a competitive necessity, managing social risks will need to become more fully embedded in corporate strategy.

Introduction

Social risk management strategies can be extremely complex undertakings that must account for and balance numerous conditions, perspectives, and variables across the business enterprise. The very nature of social risk places management teams in the challenging position of setting clear direction for a diffused function. For the complex and evolving area of social risk, corporate social responsibility programs represent an excellent mechanism for

Type	ESG-related risk or opportunity	Environmental	Social	Governance
Strategic	• Shifting customer preferences toward products that are manufactured with ethical supply chains		■	
	• Growing investor interest in ESG issues, resulting in proxy voting against the company on a range of topics (e.g., diversity, deforestation and human rights)	■	■	■
Operational	• Increased cost of raw materials due to sustainable forestry practice requirements	■		
	• Reduction of waste and raw material costs through improved manufacturing processes	■		
	• Changing weather patterns and increased natural disasters disturbing operations and business continuity	■		
Financial	• Reputation impacts and societal concerns due to a tax avoidance strategy and lack of tax transparency		■	■
	• Investment in local content to generate sustained and inclusive growth through economic diversification and employment opportunities		■	
	• Increased taxation from carbon tax regulation	■		
Compliance	• Enhanced reporting requirements for greenhouse gas emissions and energy usage	■		
	• Inaccurate or fraudulent disclosure of emissions resulting in fines and penalties and loss of consumer trust	■		■

Social Risk, Fig. 1 ESG risks and their risk categories COSO (2018)

addressing these challenges across the business enterprise (COSO 2018).

Typical categories of risk include strategic, operational, financial, and compliance. Some organizations may include a separate category for “sustainability” or “reputational” risks. However, these risks can usually be grouped in other risk categories (e.g., climate-related risks are often operational or financial in nature). Further, reputational implications are often an impact from another type of risk, rather than a risk in and of itself (e.g., reputational damage resulting from an environmental incident or pollution). In addition, many ESG (Environmental, social, and governance)-related risks are not entirely new but rather represent an additional source to an existing risk or compound the risk’s impact or likelihood of materializing. For example, climate change impacts often increase the risk of raw materials cost fluctuations, which is an existing risk for many entities (see the following figure by COSO 2018).

In the previous figure, the examples of social risks are those about customer preferences, reputation coming from tax avoidance strategy, or lack of transparency.

Recently, the Committee of Sponsoring Organizations of the Treadway Commission (COSO) and the World Business Council for Sustainable Development (WBCSD) have partnered to publish a guidance to help entities better understand the potential effects of sustainability risks and to manage and disclose them effectively (COSO 2018). According to this guide, the ESG-related risks are as represented in the following figure:

This document provides guidance for applying ERM processes to ESG-related risks. Relevant ESG-related risks will depend on the organization, which may apply a narrow definition, focusing on a selection of pertinent environmental or social risks, or a broad application that considers a myriad of issues, such as the MSCI issues set out in the following figure.

Key Issues

As regard as the field of risk, since 2013, the European Parliament, in the resolutions of 6 February 2013, have acknowledged the importance of business divulging information on sustainability such as social and environmental

	MSCI definition	Robeco definition
Environmental	Climate change, natural resources, pollution and waste and environmental opportunities	The contribution an entity makes to climate change through greenhouses gas emissions, along with waste management and energy efficiency. Given renewed efforts to combat global warming, cutting emissions and decarbonizing have become more important.
Social	Human capital, product liability, stakeholder opposition and social opportunities	Human rights, labor standards in the supply chain, any exposure to illegal child labor and more routine issues such as adherence to workplace health and safety. A social score also rises if a company is well integrated with its local community and therefore has a "social license" to operate with consent.
Governance	Corporate governance and corporate behavior	A set of rules or principles defining rights, responsibilities and expectations between different stakeholders in the governance of corporations. A well-defined corporate governance system can be used to balance or align interests between stakeholders and can work as a tool to support a company's long-term strategy.

Social Risk, Fig. 2 ESG related risks COSO (2018)

3 pillars	10 themes	37 ESG key issues	
Environment	Climate change	Carbon emissions Product carbon footprint	Financing environmental impact Climate change vulnerability
	Natural resources	Water stress Biodiversity and land use	Raw material sourcing

Governance	Corporate governance	Board Pay	Ownership Accounting
	Corporate behavior	Business ethics Anti-competitive practices Tax transparency	Corruption and instability Financial system instability

Social Risk, Fig. 3 ESG Key issues COSO (2018)

factors, with a view to identifying sustainability risks and increasing investor and consumer trust.

In particular, the subsequent EU Directive 2014/95 represents an important step toward the spread of CSR throughout European Countries. It indicates "non-financial and diversity information" to be disclosed by large companies in their annual report or in a separate document.

According to Directive 2014/95/EU, the non-financial information (NFI) to be included is essentially

information to the extent necessary for an understanding of the undertaking's development, performance, position and impact of its activity, relating to, as a minimum, environmental, social and employee matters, respect for human rights, anti-corruption and bribery matters, including:

- a brief description of the undertaking's business model;
- a description of the policies pursued by the undertaking in relation to those matters, including due diligence processes implemented;
- the outcome of those policies;

Social Risk, Fig. 4 Guidance for risk management by COSO (2018)

- the principal risks related to those matters linked to the undertaking's operations including, where relevant and proportionate, its business relationships, products or services which are likely to cause adverse impacts in those areas, and how the undertaking manages those risks;
- non-financial key performance indicators relevant to the particular business.

Furthermore, recently, the Committee of Sponsoring Organizations of the Treadway Commission (COSO) and the World Business Council for Sustainable Development (WBCSD) have partnered to publish a guidance to help entities better understand the potential effects of sustainability risks and to manage and disclose them effectively (COSO 2018).

As represented in the following figure by the COSO, the guidance provides 5 components and 20 principles and offers, at the same time, a practical approach to entities using other risk management frameworks, such as ISO 31000 or entity-specific risk management frameworks.

Also the European Commission, in its action plan, financing sustainable growth, has given a growing importance to incorporate sustainability

in the process of risk management. In this direction, the European Commission will explore the feasibility of the inclusion of risks associated with climate and other environmental factors in institutions' risk management policies and the potential calibration of capital requirements of banks as part of the Capital Requirement Regulation and Directive. The aim would be to take into account such factors, where this is justified from a risk perspective, to safeguard the coherence and effectiveness of the prudential framework and financial stability. Any recalibration of capital requirements, based on data and the assessment of the prudential risk of banks' exposures, would need to rely on and be coherent with the future EU taxonomy on sustainable activities (European Commission 2018)

Definition of Social Sustainability

Social sustainability emphasizes the societal spheres and humanity focused pillar of sustainable development. The literature has noted that it is “an open and dynamic concept which will change over time (from year to year/decade to decade) in a place” (Dempsey et al. 2009, p. 292) so that several disciplines within social sciences, such as sociology, geography, anthropology, urban studies, and so on, have engaged in discussion of the concept from different perspectives (Eizenberg and Jabareen 2017). Hence, the literature is lack of a common definition on social sustainability. However, in general, social sustainability aims to explore answers to the question of how to improve the living conditions of people. In addition, it also focuses on how the governance of the development process can be strengthened (Boström 2012). Despite the significance of social concerns and societal issues on sustainability, several scholars agree on that social sustainability was examined as a secondary concept in comparison to economic and environmental aspects of sustainable development until the late 1990s (i.e., McKenzie 2004; Boström 2012; Murphy 2012). In this vein, it is considered that economic and environmental sustainability concerns seemed to be the primary focus and social sustainability was neglected relatively, but thereafter, it has received common recognition and substantial attention. Contrary to the situation in the late 1980s and early 1990s, today, some scholars, for instance, Cuthill (2010), express that social sustainability has a crucial impact and prominent notion on economic and environmental aspects of sustainability; therefore, the concept of sustainable development derives from the social sustainability.

Situating Social Sustainability in Sustainable Development

Antecedents of the development of social sustainability go back to the 1980s (Linnenluecke and Griffiths 2010) when an awareness has been nurtured on the adverse impacts of industrialization

such as overlooking social equity or fundamental human and labor rights of employees who are the most important factor of production. As revealed from the reports by United Nations Development Programme (UNDP), in the twenty-first century, development is recognized within a more comprehensive approach assessing both economic and social aspects such as well-being of population, average income, people’s freedom, gender inequity, life expectancy, literacy, education, health, and safety (UNDP 2015). According to Human Development Report (1996: 1), development is the “end,” whereas economic growth is a “means.” Therefore, the ultimate purpose of the development should focus on society and improving the well-being of the people (Human Development Report 1996). This awareness leads to transformation of the context of development from the basis of economic growth to human development. The concept of sustainable development and one of the main pillars of this tridimensional concept, social sustainability, has proceeded under these circumstances.

The concept of sustainability has arisen through Our Common Future, a report by World Commission on Environment and Development (WCED), which is an entity of the United Nations (UN) also known as the Brundtland Commission (WCED 1987). Brundtland Commission coined the term of sustainable development and defined it as “*development that meets the needs of the present without compromising the ability of future generations to meet their own needs*” (WCED 1987, p.43). Hence, Our Common Future is a significant milestone for the development of the concept of sustainability by which economic welfare has linked to environmental coherence and social equity for the development. The report describes the concept of needs as follows: “*in particular the essential needs of the world’s poor, to which overriding priority should be given.*” Therefore, according to Our Common Future (WCED 1987), primary purposes of development are the reassurance of human needs and desires (such as nutrition, sheltering, clothing, employment) and increasing people’s quality of life above than the minimum standards of living. Moreover, the report also calls attention to the risk

of depletion of renewable and nonrenewable resources due to the pressure generated by the growth of population and productive activities. As a result, the report reveals that sustainable development can only be possible in case of the utilization of resources in harmony with the demographic, commercial, institutional, and technological developments considering of current and future needs of human beings and future generations. Under these circumstances, sustainable development is recognized as a comprehensive paradigm that contain three dimensions – namely, economic sustainability, social sustainability, and environmental sustainability. Hajirasouli and Kumarasuriyar (2016) interpret the perspective presented by the Brundtland Report's sustainable development. According to them, political system should guarantee the effective participation of citizens in the decision-making process, whereas economic system should be arranged and managed with the purpose of a sustained surplus. In addition, social system should provide resolutions of the problems and negative impacts generated from “disharmonious development” (Hajirasouli and Kumarasuriyar 2016, p.24). Thus, social sustainability is considered as a fundamental and significant component of sustainable development and efforts to conceptualize the relationship between the social dimension of sustainable development and the economic and environmental dimensions of sustainable development have begun.

Following to the widespread acceptance of the definition of sustainable development by world political, academic, and business leaders in Rio de Janeiro at the UN Conference on Environment and Development (Clark et al. 2005), in 1994, John Elkington coined the term “triple bottom line” that addresses a balanced approach integrating economic, environmental, and social interests simultaneously (Elkington 2004). To him, “a desired level of ecological, social, and economic sustainability cannot be achieved separately without at least achieving a basic level in these areas simultaneously” (Elkington 1999, p.75). Thereafter, academic studies have been incrementally conducted to provide theoretical and empirical basis for the tridimensional

sustainability practices (i.e., Dyllick and Hockerts 2002; Bansal 2005; Giddings et al. 2002; Morelli 2013). Whereas Morelli (2013) states a hierarchical model indicating high dependence of economic and social sustainability on the environment, several scholars express that economic, social, and environmental aspects of sustainability are interrelated. In regard of the interrelation of these aspects, Giddings et al. (2002: 189) highlight a symmetrical interconnection with three equal sized rings just like a Venn diagram, which symbolizes a balance and reconciliation of economic, social, and environmental interests (Fig. 1).

In this model, the risk of thinking the dimensions separately is discussed as a weakness (Giddings et al. 2002: 189). According to this argument, as the interconnection presented by separated parts of the aspects, the decision about the prioritization of a dimension generates a limitation. As a resolution of this concern, another model where the economy takes a part within the social aspect and both are embraced by the environment has been put forward (Montiel 2008) (Fig. 2).

Nested model highlights an interdependence between there dimensions of sustainable development. Accordingly, economy is depended on society and environment surrounds society and so economy (Giddings et al. 2002: 192). Thus, economy is considered as a part of human activity and

Social Sustainability, Fig. 1 Three-ring view of sustainability dimensions. (Source: Giddings et al. 2002: 189)

Social Sustainability, Fig. 2 Nested view of sustainability dimensions. (Source: Giddings et al. 2002: 192)

economic sustainability depends on social features which correspond to environment. In other words, social sustainability is directly affected by environmental sustainability and directly affects the economic sustainability.

Derived from the nested model of sustainability, social sustainability has a crucial importance to achieve sustainable development goals and requires a particular focus within the sustainability agenda. However, regarding what social sustainability refers to is still under debate and there is not a commonly recognized definition of the concept. The existing definitions reflect different study perspectives or social disciplines (Weingaertner and Moberg 2014). For instance, two sociologists Griessler and Littig (2005) focus on needs and work and express the importance of the relationship between nature and society. As Sachs (1999) states that social sustainability is considered either a requirement to continue structures in societies or a precondition for sustainable development. It is also stated that social sustainability “must rest on basic values of equity and democracy” (Sachs 1999, p.27). According to Polèse and Stren (2000), social sustainability intends to a development, and it can be possible only if balancing the evolution of civic society, which will result in a more prosperous environment. From this point of view, social integration, cultural diversity, and equity have a crucial role. In a similar vein, Barbier (1987) expresses the significance of maintaining social values including culture, equity, and social justice. Woodcraft et al. (2011) define social

sustainability as a process of creating a prosperous society, which can be able to occur through understanding the needs of people. Another definition by Hawke Research states that social sustainability refers to “a positive condition within communities and a process within communities that can achieve that condition” (McKenzie 2004, p. 23).

Instead of providing a common definition, some authors focus on the components (Colantonio 2009; Jaeger et al. 2011), interpretations (Chiu 2003), themes (McKenzie 2004), or divisions (Cuthill 2010) of social sustainability. These studies identify that the most accepted and discussed key elements of social sustainability as basic human needs including health, housing, education, and social security, social justice and equity, quality of life, diversity, social cohesion, participation and democracy, and human well-being. In addition, Vallance, Perkins, and Dixon (2011, p.342) present a threefold schema for the conceptualization of social sustainability and their work has gained widespread influence. Accordingly, their framework contains three subcategories. The first category “development sustainability” points to basic needs, the creation of social capital, justice, and so on. The second category “bridge sustainability” addresses changes in behavior to achieve bio-physical environmental goals. Finally, “maintenance sustainability” emphasizes the preservation of socio-cultural features in the face of change and the ways in which people react to those changes (Vallance et al. 2011).

Summary

Derived from abovementioned definitions and stated elements of social sustainability, it can be concluded that social sustainability contains a process for the improvement of living conditions of people. Therefore, it refers to both conditions that enable increasing the living standards and the process for progress. In this regard, social sustainability can only be achieved in case of systems have been established for physical well-being of people, equity, and citizen engagement.

Definition

Socially responsible investing (SRI) and finance is an investment strategy which considers the social, environmental, and ethical (SEE) consequences of the investment decisions within the context of financial analysis, while conventional investment strategy only focuses on the traditional risk and return considerations in the investment decision making process. It is also well known as “sustainable investing” or “responsible investing” or “social investing” or “green investing” or “ethical investing.” It seeks to make financial returns with the considerations of SEE criteria for a positive effect in the society and environment. The investors who care about the impacts of their investment funds in the society and environment are named as socially responsible investors. In general, socially responsible investors encourage the positive business impacts by applying the above SEE criteria in the investment screening process. Contemporarily, socially responsible investing has become the leading investment strategy of various investment banks and asset management companies. There are various SRI strategies have been used in the industry to achieve the SRI objectives, including negative screening; positive screening; environmental, social and governance (ESG) integration; divestment; shareholder activism; shareholder engagement; shareholder resolution; shareholder voting; impact investing; and community investing,

which will be explained in details in the following section.

Introduction

Social issues are distinguished from economic issues, which is defined to be related to people's personal lives and interactions. Some of the major social issues include, but are not limited to, alcohol and tobacco (and its laws), gambling, employee relations, minority issues, corporate governance, military goods/services, labour standards in supply chains, human rights, health and safety, bribery and corruption, stakeholder relationship management, gun rights and wars, abortion, suicide and assisted suicide, censorship, corporal punishment, drug laws, ageism/youth rights, etc. The environmental issues include climate change, climate pollution, deforestation, biodiversity, ozone depletion, nuclear issue, chemicals of concern, etc. The idea of investing to companies with high environmental scores is aiming to reduce the value of global environmental costs from their investment decisions. According to the report of the United Nations Environment Programme Finance Initiative (UNEP FI 2011), the annual environmental costs from global human activity amounted to US \$ 6.6 trillion in 2008, which equated to 11% of global GDP in 2008, and these costs include greenhouse gas (GHG) emissions, over-usage of water, air pollutions, and other unsustainable resource usages. The environmental costs are expected to reach 18% of GDP in 2050 under a "business-as-usual" scenario (UNEP FI 2011). In other words, the value of global environmental external costs from human activity is significantly high and rising. The effect of environmental externalities hence is increasing if human activity and business continues as usual. The other important issue for investors to make considerations is the ethical issues in business organizations. The ethical criteria in general include human rights, woman abortion, animal tests, pornography, gambling, third world pharmaceuticals, health care issues, genetic engineering issues, religious issues, etc. Some of the ethical issues can be interchanged

with the social issues. Literally, there is no clear definition of ethical issues in business as everyone has their own concept of righteousness; home environment, religious beliefs and traditions, and thus making ethics hard to define, but not impossible to make. The dilemma that many business owners face is the definition of business ethics, and acceptable business behaviour. Overall, SRI strategies with considerations of SEE criteria incorporate societal needs and benefits in the selection and management of investment portfolios. SIR aims to reduce the social, environmental, and ethical costs and helps the world to grow sustainability.

The start of SRI can be traced back to the Quakers who prohibited members from engaging in the slave trade in 1758 and the fiduciary investment service company managed Quakers' assets by following SRI guidelines. John Wesley (1703–1791) adopted SRI in his sermon on "the use of money" which stated that social investing is based on the fact that do not harm others through the business practices and avoid investing in industries that can harm the health of others (Antonacci 2017). The beginning era for the first public offering of socially responsible investment fund was initiated in 1928, which was a small Pioneer Fund from the USA with restrictions of investing in alcohol or tobacco (Antonacci 2017), and then following with the launch of Pax World Fund in 1971 under the objective that their profits were not generated from supporting the production of weapons (Antonacci 2017). In the 1980s, SRI played a key role in the reactions to end the apartheid government in South Africa. In 1989, representatives from the SRI industry gathered at the first SRI in the Rockies Conference to exchange ideas and gain momentum for new initiatives. In the 1990s, the focus of SRI had shifted in a large scope of issues, such as alcohol and/or tobacco stocks, mutual fund proxy disclosure, human rights, and others. Since the late 1990s, SRI has become increasingly defined as a means to promote environmentally sustainable development. Investors started to consider the effects of global climate change from the perspectives of a business and corporation. In the UK, socially responsible pension fund regulations were

constructed in 1999. The first sell-side brokerage in the world to offer SRI research was the Brazilian bank Unibanco. The service was launched in January 2001 by Unibanco SRI analyst Christopher Wells from the São Paulo headquarters of the bank. More recently, the world well-known FTSE4Good index was launched in the UK in 2002, while the UN Principles for Responsible Investment (UNPRI) was launched in 2006. To sum, the applications of SRI strategies are particularly prevalent in the contemporary financial markets.

Overview of SRI Strategies

Nowadays, socially responsible investing has become the mainstream of various asset management companies and investment banks. There are various SRI strategies that have been used in the industry to achieve the SRI objectives, including negative screening, positive screening, ESG integration, divestment, shareholder activism, shareholder engagement, shareholder resolution, shareholder voting, impact investing, and community investing. At the beginning, investment strategies are screened into negative screening and positive screening according the SEE criteria, which entails the incorporation of ESG criteria into the financial analysis. Alternatively, shareholders can engage the companies with SEE issues by initiating shareholder activism, shareholder engagement, and shareholder voting. However, the investment strategies are not limited with the above options. Additional SRI strategies, like ESG integration, divestment, positive investing, impact investing, and community investing, are also discussed at below.

Negative Screening

The mainstreaming of SRI started from small-scale “sin stocks” screening by religiously motivated investors to a variety of approaches adopted by large institutional investors and business case of SRI. Investment strategies are designed by excluding a list of companies with SEE concerns or low SEE ratings which is known as the negative screening process.

Positive Screening

Examples of positive screening include the launching of sustainability themed investment funds (e.g., renewable energies investment funds); best-in-class companies selecting which investment is made to companies who experience the highest SEE rating in the industry; selecting companies with good and positive SEE ratings on relevant criteria; and selecting companies by applying ESG integration standards.

Divestment

Divestment is the process of selling subsidiary assets, investments, or divisions in order to maximize the value of the parent company. Also known as divestiture, it is the opposite of an investment and is usually done when that subsidiary asset or division is not performing up to expectations, such as the divestment activates in the fossil fuel industry.

Shareholder Activism

Shareholder activism is a notion that shareholders attempt to have a positive influence on the management and the running of the business by engaging and communicating with the board of directors and company leaders. The shareholder actions include starting a conversation or dialogue with the corporate management team on issues which might have a negative effect on the performance of the company. It is also known as an alternative option for shareholders to see its ownership and give up hopes on the performance of the companies. Shareholders believe that engaging with the corporate management level and working cooperatively can improve the financial performance over time and enhance the well-being of both shareholders and stakeholders. People who engaged in the shareholder activism are called shareholder activists. The events of shareholder activism could include but are not limited to shareholder engagement (dialogue with management team), public campaigns, shareholder voting, and shareholder resolutions.

Shareholder Engagement

Shareholder engagement is the sub-class of shareholder activism which shareholders are aiming to

have dialogues with the company, especially with the board of directors who will receive constructive feedback on how to make improvements on the corporate governance and management matters.

Shareholder Voting

By corporate laws, shareholders have the rights to exercise their voting rights at the annual general meeting of corporation or by the shareholder proxy voting. Shareholder voting rights give you the power to elect directors at the annual general or special meetings and make your perspectives on the issues of the company management that may affect the value of your shares. The shareholder proxy voting is the term used to describe the means for shareholders to participate in a company's annual shareholders meeting, without attending the meeting. Shareholders who do not attend a meeting will have a chance to vote on the matters to be considered at the annual general meeting. Corporate bylaws typically require a quorum for voting at a shareholder meeting. A quorum is typically reached when the shareholders present or represented at the meeting own over half of the corporation's shares. Approving a resolution typically requires a simple majority of share votes. Alternately, each shareholder may have one vote, regardless of how many shares of company stock he/she owns.

Shareholder Resolutions

A shareholder resolution is a proposal submitted by shareholders for a vote at the company's annual meeting. The submission and handling of resolutions are usually following the regulatory guidance from the Securities and Exchange Commission (SEC). Shareholder resolutions have been an important part of shareholder activist campaigns. Shareholders can submit resolutions with various corporate social responsibility issues, such as nuclear power, global warming, labour relations, tobacco smoking, human rights, and animal welfare, but primarily with corporate governance, such as executive compensation, board compositions.

Impact or Community Investing

The degree of expected social impacts through investment is different based on the choice of SRI strategies. Impact investing or community investing is one of the extreme types that aims to make contributions to the conscious creation of social impact through investment. It is a sub-class of socially responsible investing which aims to make investments into society or community-based organizations. G8 social impact investment task force defined impact investing as those that intentionally target specific social objectives along with a financial return and measure the achievement of both. Impact investing is particularly targeted for the purpose of providing capital to businesses that potentially have social or environmental impacts. The capital can be in a variety of forms such as private equity, debt, working capital lines of credit, and loan guarantees. The examples of impact investing are in the fields of venture capital community, microfinance, community development finance, technology corporation development finance, and start-up businesses. Community investing institutions use investor capital to finance or guarantee loans to individuals and organizations that have historically been denied access to borrow capitals from traditional financial institutions. These loans are used for housing, small business creation, and education or personal development in the USA and UK or are made available to local financial institutions abroad to finance international community development. One of the challenges from the community investing institutions is to ensure the success of the loan and its returns for investors.

ESG Integration

Nearly 30 years ago, Rudd (1981) firstly concluded that the integration of ESG criteria in investment process can worsen portfolio diversification. Hoepner (2010) challenged his theory with a conclusion that the inclusion of ESG criteria into investment process likely worsens portfolio diversification via the first and second drivers (number of stocks, correlation of stocks), but it similarly likely improves portfolio

diversification through a reduction of the average stock's specific risk (the third driver, average specific risk of stocks). The ignorance of ESG criteria in many cases violates their fiduciary risk management duties. The integration of ESG criteria/screens in investment strategies are expected to lead to a diversification penalty, compared to otherwise identical conventional investment strategies. Over decades, authors and relevant researchers believe that ESG criteria must have a generally negative effect on portfolio diversification, because they limit the investment universe (e.g., Barnett and Salomon 2006; Renneboog et al. 2008; Rudd 1981). However, there is a robust evidence that ESG issues are publicly material and can affect shareholder value in both short and long term (UNEP FI 2011). It is argued that the impact of ESG issues on share price can be valued and quantified. The United Nations Principles for Responsible Investment (UN PRI) is one of the largest institutional investment coalitions comprising over 500 asset owners and managers representing assets of over \$18 trillion, an indication of the growing recognition of ESG integration as a value driver. The principles encourage investors, especially institutional investors, to integrate ESG factors into their investment decisions. Being signatories of UN PRI, investors are volunteering to collaborate to improve the performance of the corporate and its corporate governance and management. The activities of these asset owners have demonstrated the feasibility of ESG integration.

Summary

Overall, SRI strategies with considerations of SEE criteria incorporates societal needs and benefits in the selection and management of investment portfolios. SIR aims to reduce the social, environmental, and ethical costs and help the world to grow sustainability. While conventional investment strategies concentrate only on traditional risk and returns considerations in the decision-making process, SRI and finance considers SEE-related factors in the investment

decision-making process as discussed above. Hence, the question often arises as to whether it pays financially to be ethical or whether it matters in incorporating ESG criteria in the investment decisions. The majority debate has focused on the relationship between SRI and financial performance as to whether there is anything to gain or lose by deciding to be ethical and socially responsible in making investment decisions. Several studies have found that there is no conclusive evidence as to whether the performance of SRI outperforms those of traditional investment and vice versa. The discussion is still ongoing from the 2000s. Despite this, socially responsible investing has a growing trend in the current financial markets and has become an important principle guiding the investment strategies of various investment funds and accounts in the market.

Socially Responsible Investment (SRI)

Belén Díaz Díaz and Rebeca García Ramos
Department of Business Administration,
University of Cantabria, Santander, Cantabria,
Spain

Synonyms

Ethical investment; Responsible investment;
Social investment; SRI

Definition

Socially responsible investment (SRI) consists of integrating environmental, social, and governance principles into the selection and management of investment portfolios (ESG principles).

SRI means choosing investment portfolios that include responsible companies without needing to bear a higher cost, because socially responsible investment funds (SRIFs) are just as profitable as conventional ones.

SRI implies adding a fourth criterion to the three traditional investment criteria: liquidity, profitability, and risk. The fourth criterion concerns asking questions about the social and environmental impact of the companies into which investors put their money. Investors are beginning to acknowledge that factors related to corporate social responsibility (CSR) have an influence on the future performance of companies, thereby affecting the yields generated by their portfolios. As a result, they are beginning to take account of CSR-associated risks in the management of their portfolios, and in order to improve their chances

of attracting capital, companies are being obliged to demonstrate market-oriented but also responsible behavior.

- Rewarding the companies with the best behavior
- Ruling out those that harm the environment or violate human and/or employment rights in the course of their business operations
- Maintaining an ongoing dialogue with the company's administrative/management bodies about matters relating to its CSR policies
- Exercising the political rights inherent to the ownership of the company's shares

Introduction

Historically, SRI has its origins in the nineteenth century. At that time, in countries such as the United Kingdom and the United States, this type of investment was linked to the financial activities of some religious communities, such as the Quakers, who rejected any investment in activities involving the slave trade or alcohol (Balaguer et al. 2007).

But the current form of SRI stems largely from the political movements of the 1960s and 1970s in the US, when apartheid in South Africa and later the Vietnam War prompted some groups to avoid investments in companies that had connections with these matters. It was in this way that socially responsible investment became defined by its exclusion of certain activities.

This concept of exclusion, linked to the notion of negative discrimination, continues to be one of the distinctive features of this type of investment. Naturally, the reasons for such exclusions vary considerably and are not uniform across all countries; in the United States, almost 100% of socially responsible investment funds (SRIFs) penalize the tobacco industry, whereas in the United Kingdom, arms manufacturers and animal testing are the primary reasons for "censure" by the SRIFs (Sánchez et al. 2002).

As SRI evolved, new company selection criteria were considered. Although SRI was originally motivated by essentially moral, ideological, and social concerns and focused on boycotting or excluding certain business sectors from investment portfolios,

over time, SRI has moved from a negative approach (of excluding companies) toward a more positive one that seeks to include more exemplary companies in investment portfolios. This new direction has gained strength in recent years, and with its longer term, more financially oriented perspective, we can describe it as sustainable investment. It seeks to incorporate, in an integrated manner, economic, environmental, and social criteria into the evaluation of financial portfolios, investing in the best-in-class companies in each sector.

Key Issues

SRI may be based on the following investment strategies:

- 1. **Negative screening/exclusion.** This strategy excludes some investments in certain companies, sectors, or countries.
- 2. **Positive/best-in-class screening.** Investments are chosen in the industries, companies, or projects with the best performance in terms of the ESG criteria.
- 3. **International ESG standards-based screening.** Selection of investments that comply with international standards-based on ESG criteria, such as those published by the OECD, the UN, and UN agencies (including Global Compact, ILO, UNICEF, and UNHCR).
- 4. **Integration of ESG factors.** Explicit, systematic inclusion of ESG factors by asset managers in their traditional financial analysis.
- 5. **Sustainability-themed investment.** Investment in themes or assets linked to sustainable development (e.g., clean energy or sustainable agriculture).
- 6. **Impact/community investment.** Impact investments are investments made in companies, organizations, and funds that are intended to generate a social and environmental impact alongside a financial return. According to the Global Impact Investing Network (GIIN), impact investments can be made in emerging markets as well as in developed markets and target a range of returns from below market to market rate, depending on the circumstances of each. But these investments differ from

philanthropy in that the investor retains ownership of the asset and expects a positive financial return (GIIN, 2012).

Impact investment also includes micro-financing, community investment, social enterprise funds, and solidarity funds. We must not confuse **solidarity funds** with **socially responsible funds**. Funds known as solidarity funds assign a percentage of the management commission to certain charitable organizations or non-governmental bodies, even though they may not meet certain criteria for selecting investments.

- 7. **Corporate engagement and shareholder action.** This is a long-term process that seeks to influence a company’s behavior and increase transparency. It consists of using shareholder power to influence business behavior through active participation in the company (e.g., communication with the managers and/or the board of directors), by shareholders submitting proposals, and proxy voting under ESG guidelines. As shareholders, investors exercise their right to vote and attempt to engage with and/or exert pressure on the company to persuade it to adopt a clear position with regard to its policies on sustainable development issues.

Negative and Positive Criteria Principles Used in SRI

Negative or exclusion criteria	Positive or approval criteria
Environmental destruction	Promotion of local or community development in developing countries
Arms/nuclear industry	Environmental protection
Alcohol and tobacco industries	Information transparency
Child labor exploitation	Respect for basic workers’ rights
Betting industry	Projects harmoniously integrated into the local community
Use of aggressive or offensive advertising	
Promotion of violence	
Pornography industry

Principles for Responsible Investment (UN)

In 2005, Kofi Annan, the United Nations General Secretary, invited global institutional investment leaders to agree upon the development of the Principles for Responsible Investment (PRI). In 2006, 6 principles were approved following several meetings of 20 leading institutional investors from 12 countries and dozens of experts from different sectors in the investment field.

The main purpose of the PRIs is to provide a structural framework for the integration of the ESG criteria (environmental, social and corporate governance) into decision-making processes and asset management and to guarantee the ethical purposes of the investment funds that subscribe to them. Adoption of the principles is entirely voluntary, and the signatories, whether they were institutional investors, asset managers, or financial services providers, pledged to abide by them.

Principles for Responsible Investment

Principle 1: We will incorporate ESG issues into investment analysis and decision-making processes.

Principle 2: We will be active owners and incorporate ESG issues into our ownership policies and practices.

Principle 3: We will seek appropriate disclosure on ESG issues by the entities in which we invest.

Principle 4: We will promote acceptance and implementation of the Principles within the investment industry.

Principle 5: We will work together to enhance our effectiveness in implementing the Principles.

Principle 6: We will each report on our activities and progress toward implementing the Principles

How to Appraise Companies to Decide Whether They Should Form Part of the SRI

Social rating agencies are for-profit or nonprofit organizations that have developed research methodologies for examining business aspects that fall

within the sphere of social and environmental impacts and for studying the policies, processes, procedures, and systems set up to mitigate the negative impacts generated during the course of the company's business operation.

The independence of these agencies lies in the fact that their services are paid for by the parties that make use of the information they provide (investors, fund managers) unlike audits, which are paid for by the company that is audited.

Both SRI funds and stock market sustainability indexes make use of the company vetting reports issued by these agencies.

The methodology employed to obtain the data is based on the compilation and analysis of corporate information: information provided by the company (financial report, sustainability reports, etc.), questionnaires sent directly to the company, and any necessary verification by external sources. This information is used to establish a social rating.

Most of the longer established social ratings agencies (that sprung up in the 1980s and 1990s) began as wholly independent firms, specializing in social and environmental data, and generally unconnected to the large financial groups. With the great numbers of investors entering the SRI field, large financial groups, such as Morgan Stanley, acquired some of these agencies with a view to enhancing their nonfinancial information management.

The main ratings agencies are:

- **MSCI** (Morgan Stanley Capital International) which set up major sustainability stock market indexes in 2010, including the MSCI ESG Indexes, and in 2014, it acquired **KLD Research & Analytics Inc.**

For more information: <https://www.msci.com/indexes>

- **RobecoSAM.** Founded in 1995, RobecoSAM is an investment specialist focused exclusively on sustainable investing. To this end, it offers a comprehensive palette of products including in-house asset management, Sustainability Indices, corporate sustainability assessments, active ownership and engagement, and

customized portfolio benchmarking solutions. Since 1999, they have published a family of sustainability indexes, such as the Dow Jones Sustainability Index family (DJSI), S&P ESG Index Family, S&P Fossil Fuel Free Index family, and ESG factor Indices.

For more information: <https://www.robeco.com/en/about-us/>

- **Vigeo Eiris** manages ESG indices that are frequently referenced across the financial industry such as Euronext Vigeo Eiris Indices, Ethibel Sustainability Indices (ESI), Vigeo Eiris Best Emerging Market (EM) Performers ranking, and CAC 40[®] Governance index.

For more: <http://vigeo-eiris.com/>

- **Sustainalytics** is a global leader in ESG and corporate governance research information and ratings since 1992.

For more information: <http://sustainalytics.com>

Future Directions

SRI is currently considered to be among the most dynamic and innovative types of investment in the investment funds sector. Indeed, it is possible to assert that capital markets today have understood the transcendent importance of social responsibility in business administration and risk management. This notable growth and development of SRI in international financial markets has been driven by several factors such as:

- The emergence of socially responsible stock markets indexes (such as the Dow Jones Sustainability Index).
- Evidence proving that SRIFs do not generate lower returns.
- The recent more considerate approach adopted by investors toward social and environmental issues.
- Government support for SRI in countries such as the United Kingdom, France, and Germany, where the pension plans are required to publish their policies on SRI, and in the Netherlands, where tax incentives exist for this type of investment.

These factors will contribute to the continuing growth of SRI in the future.

Socially responsible marketing

Definition

The traditional marketing view is based upon the premise that marketing process is technical rather than moral in nature via concentrating on converting the customer demands into products regardless of its ethical or moral effects (Crane and Desmon 2002). However, Philip Kotler whose philosophy relying on what is good for customers might not be good for society has incorporated two important aspects into the marketing science, (a) morality and (b) society. In that vein, Kotler has broadened the marketing field by means of extending marketing practices into nonbusiness areas (e.g., marketing of social ideas, persons, and causes) and revising the marketing concept with the considerations of societal orientation (Kotler 1972). In other words, Kotler (1972) has redefined the marketing concept through the way of enlarging its existent key elements of customer satisfaction and profitability with an additional element of “long-run customer welfare.” In this sense, societal or socially responsible marketing refers to “the incorporation of societal-based considerations in the design and implementation of marketing strategies whether they are designed to influence the acceptability of the products, services, social ideas, or an organization’s attempts to relate to all of its publics” (El-Ansary 1974). The logic behind this phenomenon is that the lack of social welfare comes with the dark side of the marketing such as environmental pollution owing to car purchases and health issues due to the excessive consumption of tobacco and alcohol products. Therefore, the concept of societal marketing was aimed to reconstruct the marketing arena via including ethical and societal considerations into the practices. In other words, societal marketing notion describes that a firm should design marketing practices via taking into consideration three elements: (a) customer satisfaction, (b) firm profitability, and (c) long-term human welfare.

Key Issues

Relying upon the societal marketing concept, Kotler (1972) has also classified

products with an intent of understanding whether they are appropriate to have societal orientation indeed. These four groupings of products depend on the benefits in the sense of providing short-term customer satisfaction or long-term consumer welfare: (a) deficient products, offering any short-term or long-term benefits to the customers; (b) salutary products, addressing low immediate demands and attractions but appealing to long-run consumer benefits; (c) pleasing products, giving strong feeling of satisfaction to the customer but having potential to be harmful for consumer welfare in the long term; and (d) desirable products, providing both customer delight immediately and long-term customer welfare. Within this framework, Philip Kotler suggests eliminating the deficient products from company products list immediately, while he advocates to make modification on both salutary and pleasing products with an aim of transforming them into the desirable products, which in fact constitutes the eventual purpose of marketing practices.

The central premise behind the notion of societal marketing relies upon the consideration that an enlightened marketer should be aware of the socially responsible practices which are good for their customers as well as for their business in the long run. Since marketing term is regarded as selling, influencing, and persuading in the minds of people much more than satisfying the human needs, the incorporation of societal orientation was the great contribution to the field. Societal marketing practices may involve such examples like finding out the balance between customer orientation and the quality of the ecology, introducing environmentally responsible products or services, designing products concerning its ethical and moral aspects, integrating communication systems intending to educate consumers, and providing reliable information in their advertising appeals (El-Ansary 1974). For instance, one of the advertisements of Budweiser was showing how their company was established by its immigrant founder. Also, Coca Cola’s societal marketing campaign was successful in delivering the message of cultural harmony and showing the advertisement that different people from different

ethnicities were singing “America is Beautiful.” Besides, The Body Shop, which is a British cosmetics company, strongly advocates human rights and climate change. Further, another example can be given for AVON, which is a beauty and cosmetics company and is well known with its famous societal marketing concept through the sale of pink ribbons for the campaign called as “National Breast Cancer Foundation.”

In fact, the phenomenon of societal marketing provides several advantages to the companies such as helping to improve company reputation, gaining competitive advantage over the rivals, decreasing customer retention and building long-term relationships with the customers, enhancing sales and market share, increasing company growth and profitability in the long run, using company resources in an efficient way, and improving the life quality of people in the society. However, it is also vital to note that the concepts of social marketing and societal marketing are related in some ways but are different indeed. While social marketing is aimed to make a social change via attracting the attention of people, societal marketing is more inclined to shape marketing decisions and strategies within a company by considering three main concerns (i.e., customer satisfaction, firm profitability, and society welfare).

The Historical Evolution of the Concept

In the 1990s, environmental problems and harmful effects of products on consumers were highly placed on the media, which, in turn, increases the popularity of the issues such as the consumerism and environmentalism in the society (Peattie 1995). In this sense, companies faced with the challenge that conducting social and environmental strategies will gain both reputation and profit to them as a response to customer reactions (Walley and Whitehead 1994). However, even though environmental issues have been central of the attention in the 1990s, it has showed an exponential increase in the 2000s (Chabowski et al. 2011). In this context, an accumulated body of research paid great attention to the societal

issues in the marketing field in fact dated back to the 1960s with the emergence of the concept of “societal marketing” (Kotler and Levy 1969). Besides, several researchers have also introduced new concepts to the extant literature with the effect of environmentalism and consumerism movements among consumers such as “environmentalism” (e.g., Drumwright 1994), “social marketing” (e.g., Andreasen 1994), “enviropreneurialism” (e.g., Menon and Menon 1997), and “corporate social responsibility” (e.g., Brown and Dacin 1997).

Summary

Societal marketing concept, which has been introduced to the pertinent literature in the 1960s by Philip Kotler, aims to revise the traditional view of marketing. With the effects of consumerism and environmentalism movements in the society, it was great attempt to introduce this new phenomenon of “societal marketing,” which relies upon the balance between three major elements for companies: (a) customer satisfaction, (b) company profitability, and (c) society long-term welfare in designing marketing practices. In this sense, this concept is intended to increase market share and maximize profitability by means of integrating social and environmental concerns into the marketing strategies, which, in turn, result in building long-term relationships with customers and enhancing the human welfare within the society.

Soft Law

Benedict Sheehy
Canberra Law School, University of Canberra,
Bruce, Australian Capital Territory, Canberra,
ACT, Australia

Synonyms

International law; Law; Regulation

Definition

Soft law is a category of law that is not enforced by public authorities. Rather, it is type of norms or principles that are an expression of what is generally accepted among parties to whom it applies. As such, it is intended to influence the conduct of parties rather than force parties into certain types of behaviors that comply with the rules (Cini 2000). The term “soft law” covers a wide range of instruments that have different focuses. As a result, it is difficult to formulate a comprehensive, coherent set of criteria to include an instrument in the category of soft law. Soft law includes rules, principles, norms, and prescriptions and can be found in contracts, resolutions, recommendations, codes of conduct, and whole host of other instruments such as standards and guide (Boyle 1999; Weeks 2016; Sheehy 2019). In summary, soft law can be defined as “normative provisions contained in non-binding texts” (Shelton 2000).

The Nature of Soft Law

Soft law is not a clearly delimited and defined term. Following law’s binary principles – legal or illegal – legal scholars may look to a simple binary definition of “binding/nonbinding” to distinguish hard law from soft law (Shelton 2000). Indeed, one group of legal scholars, the positivists generally deny that “soft law” is a legal category, since by their definition of law anything which is law is binding (Klabbers 1998). A better approach to soft law is defining it as a residual category: “the realm of ‘soft law’ begins once legal arrangements are weakened along one or more of the dimensions of obligation, precision, and delegation” (Abbott and Snidal 2000).

One approach to understanding the concept is by illustrating it through examples. Soft law includes a wide range of instruments, and so it may be best understood as a spectrum of instruments rather than a set category of similar legal objects. Soft law may be described along a spectrum of “softness.” So, soft law may range from mere guidance or statements on behavior at one end of the spectrum to being a set of mandatory

prescriptions and prohibitions which are all but enforceable through the courts on the other (Shelton 2000).

Thus, an understanding of soft law may be developed by examining the source of the legal instrument. Traditional hard law is considered an authoritative pronouncement backed up by force. Soft law instruments, by way of contrast may issue from private standard setting bodies, industry associations, international public law bodies, or other organizations. Even determination of the source of the law may be insufficient as some instruments considered soft law may be delegated legislation/regulation or soft law, dependent upon whether a government expressly authorized creation (Alarie et al. 2014).

A second approach to understanding soft law comes from an analysis of legal effect more broadly. If an instrument gives legal effect it is not soft law. Rather, it is clearly hard law as it engages with legal rights and duties within a public legal system. It is not that soft law cannot be within a public legal system. Where it is within a public legal system, it must be executive or administrative in nature and not legislative (McGarry 1944).

A third approach to tackling the concept of soft law comes from an attempt to categorize instruments. Baldwin and Houghton have proposed eight categories. These are (1) procedural rules, (2) interpretive guides, (3) instructions to officials, (4) prescriptive/evidential rules, (5) commendatory rules, (6) voluntary codes, (7) rules of practice, management or operation, and (8) consultative devices and administrative pronouncements (Baldwin and Houghton 1986). Such classification of instruments, however, does not amount to a definition of soft law.

A fourth approach which some may try is classifying soft law according to substantive focus or jurisdiction. Soft law, however, can address any area of legal concern, from environmental matters to prices and warranty policies in consumer affairs. Further, soft law may be used in the context of local governments, international public actors, or specific industries by private actors such as industry associations. Accordingly, neither the substantive focus nor jurisdiction is

adequate to categorize a rule, norm, or principle as “soft law.”

Consequently, soft law often has an aspirational aim or persuasive intent, focused on a class of actors with a view of changing or confirming accepted behavior. To understand what effect a document is intended to have requires analysis of the overall content, the language of the instrument to determine the audience, the parties, the specific behaviors under normative review, and the proposed effect. Most significant in soft law is that it excludes a legal effect. That is, soft law is not expected to change or threaten the legal position of actors who fail to comply with the prescriptions and prohibitions contained in a soft law instrument.

Soft law is a bridge between law and policy (Sossin and Smith 2002). Soft law encompasses both policy and a particular set of policy instruments that intend to change behavior. An essential status of the executive policy is that the administration does not establish regulatory rules for guiding decision-making, especially when administering the legislation. To the extent that “regulatory rules” can be equated to “influencing behavior,” policy and soft law are similar. However, the policy covers a broader range of documents than soft law. Soft law has become the “principal administrative mechanism used to elaborate the legal standards and political and other values underlying bureaucratic decision-making” (Sossin and Smith 2002). The bureaucratic transaction costs of creating soft law may in some instances be lower than the costs of creating hard law.

Advantages and Disadvantages of Soft Law

Soft law has many practical advantages. It is more easily developed and amended as it does not rely on the complex and cumbersome processes involved in hard law. No legislature is involved and the politics of competing recognized political parties are not in operation. As a result, soft law instruments can be drafted and disseminated more easily. Furthermore, often the intended effects of hard law do not eventuate

or only partially. In addition, events in the environment such as changes in markets or regulations mean that hard law is no longer appropriate. In such instances, the appropriate solution is some type of law reform and amendment. As with the initial legislative process, however, the process of reforming hard law is equally difficult. Soft law, being an extra-legislative type of law, is more easily amended to address unintended consequences or changes in the environment (Baldwin and Houghton 1986).

In addition, soft law allows a collaborative approach to be taken including greater interaction between the public and private sectors. As a result, soft law is more readily tailored to a specific problem and understood and accepted by the relevant actors. Further, soft law, to a greater extent than hard legislation, can provide innovative solutions that are fitted to the needs of individual industries, government agencies, or other actors (Aronson 2007).

Another benefit of soft law is that it allows states to be more ambitious in identifying desired behavior and engaging more intimately with actors than they would be able to if they had enforcement powers. A further benefit is that soft law instruments are better able to address diversity among actors and are available to non-state actors, such as international secretariats, business associations, and nongovernmental organizations (NGOs) (Kirton and Trebilcock 2017). Thus a wider range of actors are able to develop regulation suited to their own needs and constituencies.

Abbott and Snidal argue that in the international arena, states prefer soft law where contracting is difficult because of the costs associated with the number of parties involved, matters of factual uncertainty, the political challenge of domestic ratification, managing the implications of engaging in politically charged issues, and basic issues of distributional asymmetries (Abbott and Snidal 2004). In these contexts, “states can limit their legal obligation through hortatory language, exceptions, reservations and the like” (Abbott and Snidal 2004).

Soft law is not a panacea for the problems of hard law. It has its own drawbacks. Perhaps the main weakness of soft law is its lack of public authoritative enforcement mechanisms. That is, where a party has breached a soft law, one cannot bring that party to a court or tribunal to have rights and duties adjudicated and a remedy granted. Further, soft law instruments may not attract significant resources because they do not require the expensive infrastructure of public law, such as courts, inspectors, and the like. The lack of resources has additional ramifications, as, for example, a lack of regular updating and poorly developed reforms. Finally, soft law by nature relies on discretion of regulatory parties. It may in certain instance lead to unnecessarily higher compliance standards (Baldwin and Houghton 1986), or insufficiently stringent requirements.

As a result of these weaknesses, publicly promulgated soft law instruments may be found to permit a wider range of activities as compliant than were originally intended (Abbott and Snidal 2000; Reisman 1992). A further weakness is when soft law is treated as if it were hard law. Such treatment leads to potential misuse (Raz 1979).

Soft law as nonbinding rules interprets or informs our understanding of binding legal rules to create expectations about future conduct.

Summary

Soft law is useful in that it establishes norms of accepted or preferred behavior. It provides information and guidance to parties, both public authorities and private parties, that can be useful to courts, tribunals, and other regulatory bodies as well as to managers, civil society actors such as NGOs, and industry associations.

Soft law instruments come in a wide variety of types, from codes of conduct to general principles. Further, they are used in wide array of contexts – from local government pronouncements to international public instruments. Finally, they can be found in all areas of regulatory endeavor from environmental controls to consumer products to guidance to governmental bodies.

Solar as a Sustainable Energy

Mousumi Roy

Civil and Environmental Engineering, University of Connecticut, Storrs, CT, USA

Synonyms

Concentrating solar power; Energy from solar photovoltaic; Renewable energy; Sustainable energy

Definition

Solar energy is clean and renewable energy that uses sun as a power source. Solar energy can be harnessed using various solar technology for meeting residential, commercial, and industrial needs for thermal, electrical, and other forms of energy in a sustainable way. Two types of solar energy applications are available – passive and active systems. For the passive system, solar energy can be collected without using special mechanical devices or equipment. Greenhouses and sunrooms are common examples. Residential and industrial buildings can be designed to absorb and retain heat from the sun. On the other hand, in the active system, solar energy is collected using solar panels comprised of solar photovoltaic (PV) cells. Various technologies to capture and transforming it to thermal and electrical energy have developed over the years, such as Parabolic Trough, Concentrating Solar Power Tower, Dish Stirling, etc. The main goals are to increase efficiency and reduce costs.

The growth of solar energy throughout the world has been significant in the last two decades. Asian countries with high energy demand have been investing substantially in solar and other

renewable energy to reduce their dependency in fossil fuel and improve climate and health of their citizens. Continuous efforts are reducing global warming, although not successful in meeting the Sustainable Development Goals of the Paris Agreement. China and the United States continue to be the world leaders in solar energy production. During the last decade, the growth of solar energy was highest among all renewable energy. The goal is to make the cost of solar energy as competitive as fossil fuel to help the solar energy market grow.

Solar as a Sustainable Energy

Solar energy is virtually inexhaustible and most abundant energy resources – earth receives more power from the sun in 1 h than global energy needs for 1 year. Even with a 10% efficient solar conversion system covering 0.16% of the land of the earth would provide 20 TW of power, nearly twice the world's consumption rate of fossil energy and an equivalent 20,000 1-GW nuclear fission plant (Rajeshwar et al. 2008).

The applications of solar energy are innumerable – it can be used for cooking, heating, water treatment, generating electricity, agriculture and urban planning, transportation, and many more. The first solar cell was built in Bell Laboratories in 1954, starting the new era of clean energy production (This Month in Physics History n.d.). However, the adoption of solar energy in the society had been slow due to many factors such as low efficiency, availability of technology, and relatively high cost compared to the energy produced by fossil fuel. Over the years, scientific communities and consumers became aware of the adverse effects of fossil fuel and pursued sustainable and renewable energy sources. Solar energy is the most abundant renewable carbon-free resource among the other renewable energy options.

Over the last decade, global energy consumption proliferated, reaching twice on average, and the demand is expected to peak between 2020 and 2025 (World Energy Scenario 2019 n.d.). Three of the Sustainable Development Goals (SDGs) for energy, namely to achieve universal access to energy, to reduce the severe health impacts of air

pollution, and to tackle climate change by meeting the Paris Agreement on climate change of below 2 °C climate goal are yet to be met (United Nations Sustainable Development [n.d.](#)). The Sustainable Development Scenario (SDS) report has provided an outline to bring the world back to track in achieving these goals. Renewable energy such as solar and wind is predicted to significantly meet these SDGs (Renewables – World Energy Outlook 2019 – Analysis [n.d.](#)).

Among Asian Countries, China and India continue to maintain strong economic growth with high energy demand. China's energy market is currently the largest among global contenders due to its continuous mid-single-digit growth rate. To meet the high energy demand, China continues to escalate renewable energy generation. China is anticipating that the renewables will become its primary energy source by 2050. The government is using technology, innovation, and power-market reform to achieve it. China has spent more on cleaning up its energy system in recent years than to the United States and European Union combined. They are the largest consumer of solar PV and expected to account for almost half of the global distributed PV. China's PV capacity is expected to reach at least 400 GW to provide 10% of its primary energy need by 2030 (Sweerts et al. [2019](#)).

Similarly, India is exploring its vast renewable energy potential and investing more in solar power than coal. However, coal remains to be the primary energy source for India at present. In 2019, a 58% share of new capacity in renewable energy was invested in India, and a goal was set for 20 GW of solar installation by 2022 (Singh and Pal [2020](#)). The goal was achieved 4 years ahead of time, and the new goal was set to reach 100 GW by investing \$100 billion by 2022. Among other Asian countries, Japan and South Korea are at the forefront to drive the growth of solar PVs (Renewables – World Energy Outlook 2019 – Analysis [n.d.](#)).

Most of the African countries are in dire need of energy production and supply. The potential of solar energy production is very high since Africa receives the most sun during a year that any other continent. Although production and usage of solar

energy are not very high yet, abundant natural resources coupled with tremendous growth opportunities are attracting investments in renewable energy production, including Foreign Direct Investment – a \$32 billion investment was reached in 2018 (World Energy Council [n.d.](#)). International collaboration with developed regions and emerging markets such as China and India also have grown substantially in recent years.

The European Union and the United States were at the forefront of research and development (R & D) of renewable energy and provided leadership in the expansion of solar energy. The clean-energy investment in the United States was increased by 12% (\$64.2 billion) in 2018 (World Energy Council [n.d.](#)). The U.S. Energy Department is committed to expanding the solar energy market by facilitating R&D effort and manufacturing for the nation's solar energy resources. Among other renewable energy, the demand for solar energy in the United States is very high, and the amount of solar power installed has increased more than 23 times over the past decade. Over 29% of all new generating capacity added to the US electrical grid in 2015 was solar (Solar [n.d.](#)).

In recent years, the adoption of supportive energy policies and reduced cost for solar photovoltaic and other renewables has led to the progress of the clean energy that is less carbon-intensive. The production of solar PV improved by 31% in 2018 among all renewable technologies. Between 2019 and 2024, renewable power capacity is expected to grow 50%, where solar PVs is projected to account for almost 60% of the expected growth (Renewables – World Energy Outlook 2019 – Analysis [n.d.](#)).

As a sustainable energy source, solar energy is abundant and environmentally friendly since it does not release CO₂, SO₂, or similar pollutants in the environment. However, there are a few drawbacks, such as availability of power during nighttime and reduction of energy production during stormy or rainy weather. These disadvantages are currently being addressed, and various solutions are being experimented.

Two main obstacles for solar energy to meet its full potential are the conversion capacity and cost

(Crabtree and Lewis 2007). The scientific community, department of energy, and other policymakers have been instrumental in making significant progress in addressing both issues. The progress in solar energy technology and the associated cost will be discussed in the next section, followed by the summary and conclusion.

Solar Energy Technology

Solar energy technology has tremendous potential to produce clean energy to meet the world's demand. However, solar science is a relatively new field compared to fossil fuel science that have been developed over 250 years stimulated by industrial revolutions and the abundance of fossil fuel (Crabtree and Lewis 2007). This technology was driven by the oil crisis in the 1970s and has evolved and experienced tremendous growth in the last two decades. Solar PVs, solar heating and cooling, and solar thermal electricity are well known around the world. The modular design and scalability make solar PVs popular among consumers. However, availability, the geography of the land, and weather condition affects solar energy production capacity.

Solar panels, voltage controllers, blowers, pumps, and other mechanical and electrical equipment are used to transform the captured solar energy into heat and electricity. The two main categories of solar energy technologies are solar PVs and Concentrating Solar Power (CSP). The solar PVs can be installed as roof top panels on residential or commercial buildings, or ground mounted for utility suppliers. Besides solar PVs, solar energy is generated and stored in solar-thermal facilities similar to traditional fossil-fueled power plants. These are called Concentrating Solar-Thermal Power (CSP) systems, which generate clean electricity and heat for industrial, commercial, and residential uses. These facilities utilize different types of designs, such as *Parabolic Trough*, *CSP Tower*, and *Dish Stirling* for capturing solar power. Efficiencies of solar energy systems vary between 15% (for solar PVs) ("Solar

Panel Efficiency," 2020) and 30% (for Dish Stirling design) (Singh and Kumar 2018). These different types of solar technologies and models are described in brief.

Solar PV

Solar PV cells are made of glass with a back-sheet, framed with aluminum. The amount of sun that can be captured by a cell is dependent upon a few factors – tilt or pitch, orientation or azimuth, and shade. Tilt and orientation are measured in degrees relative to the horizon and North, respectively. The absence of nearby trees and buildings provides ideal shading. The location of the solar system and weather conditions, such as the presence of cloud also affect the amount of energy production. Another two factors are insolation and irradiance. Insolation is a measure for the amount of sunlight a property gets over time in watts-hour per square meter, and irradiance is used to measure the amount of sun exposure in watts per square meter. Google has estimated that 79% of all homes in the United States have adequate roof space and receive sufficient sunlight. National Renewable Energy Laboratory has estimated that nearly 40% of all energy use can be produced by rooftop solar panels, including homes, businesses, factories, and other structures (Rauschenbach 1980).

There are many variations of solar PV systems that are available to meet social and consumer's needs. Some of them are as follows:

- Off-grid or on-grid system
- Building-integrated or rack-mounted system
- Residential or utility systems
- Distributed or centralized systems
- Rooftop or ground-mounted systems
- Tracking or fixed-tilt systems
- New constructed or retrofitted systems

The versatility and scalability have helped solar PVs to gain popularity. Solar PV is expected to have the fastest growth among all renewable energy sources.

Concentrating Solar Power (CSP)

A Concentrating Solar Power (CSP) infrastructure utilizes heat produced by concentrating solar power and convert it into electricity. Various designs are available for concentrating solar power. A Parabolic Trough design consists of mirrors that are curved as a parabola in two dimensions and straight in the other dimension. If an object is placed along the focal line, it will be heated up by the sunlight – it can be used as a solar cooker. For large-scale applications, heat is collected in fluid running through a tube and can be used to drive machinery or generate electricity.

For a CSP Tower design, a large number of mirrors are used to concentrate solar beam on a receiver built in a centrally located tower. The heat generated (with a temperature between 400 °C and 1000 °C) is converted into electricity that can be stored for future use. A dish-Stirling system uses a large reflective parabolic dish to concentrate the solar heat to a receiver which then transforms it to usable form by using Stirling engine (Dish/Engine System Concentrating Solar Power Basics [n.d.](#)). The largest CSP in the world is located at Morocco with an electrical capacity of 510 Mega Watts (MW), followed by Ivanpah Solar Electric Generating System in the United States with a capacity of 392 MW of clean electricity. It can power 94,400 average American homes. Most of the power generated Ivanpah power plant will be sold to Pacific Gas & Electric and Southern California Edison Company (Celebrating the Completion of the World's Largest Concentrating Solar Power Plant [n.d.](#)).

The CSP plants and the power generation processes are durable and reliable. The Middle East and North Africa (MENA) region has an excellent solar resource condition, and a CSP Plant project called *enerMENA* was funded by German Federal Foreign Office. This project is a collaboration between the German Aerospace Center (DLR) and 45 partners from MENA regions (*enerMENA* [n.d.](#)). The World Bank's Energy Sector Management Assistance Program released its Global Solar Atlas 2.0, which indicates Direct Normal Irradiance (DNI) for each country and region. Western USA, Southern Africa,

Australia, and parts of South America are suitable for establishing CSP plants due to the high DNI. Global Solar Atlas helps policymakers and investors in making decisions based on the downloadable dataset and online queries. The cost of energy generate from CSP continues to drop over time – currently, it ranges from \$150/MWh to \$200/MWh.

CSPs can also be used for desalinization of water as a byproduct of the electricity generation process. An increase of 8% of CSP generation was estimated in 2018. Although CSP power plants produce clean energy, there are some environmental impact such as vast land use, water consumption, visual impact, noise produced by the cooling towers, smell, fire hazard and glint. Most of these adversities can be controlled by locating the CSP plants in arid/desert areas. However, the glint and glare of reflected light from CSP systems need to be considered if they are located close to the airport or flight path (FAA-Airport-Solar-Guide-2018 [n.d.](#)).

A recent meta-study of lifecycle analysis for CSP estimated that including building materials, the greenhouse gas emissions (carbon dioxide equivalent) from CSP electricity is 26 g/kWh of power. The overall environmental impact of CSP is very similar to that of other renewable energy sources. A few examples of CSP plants are Mojave solar project in California, USA, Ouarzazate solar power station in Morocco, Solnova solar power station in Spain, and Supcon solar plant in China.

Cost of Solar Energy

The low cost of fossil fuel, such as coal, has been its main advantage over solar energy. However, a study has shown that the air and water pollution generated by fossil was related to the life cycle costs and public health effect such as breathing problem, neurological damage, heart attack, cancer, premature death, etc., and the cost for coal was estimated as \$74.6 billion every year (Epstein et al. 2011). Renewable energy will eliminate this indirect cost of fossil fuel.

With the advancement of solar energy technology, the cost of clean energy continues to fall, and

solar energy is increasingly becoming a viable option for consumers. Supportive energy policies are also assisting in the expansion of solar energy in residential, commercial, and industrial arena. New utility business models such as *pay-as-you-go* (Change 2017) solar solution in Africa are useful for start-up energy entrepreneurs of small and medium sizes to provide utility services such as cooking, internet access, and water to larger portion of the population some of which were unreachable earlier by traditional grid system. Many solar energy users have become prosumers and have been exporting excess electricity produced by their solar panels back to the grid and getting a refund on their electricity cost.

SunShot Initiative was launched in 2011 by the US Department of Energy to compete with the fossil fuel cost. The solar energy Technology Office (SETO) funds advancement in solar PV through two competitive outlets, SunShot National Laboratory Multiyear Partnership (SuNLaMP) and Funding Opportunity Announcements for research projects at university, private companies, and national laboratories. Department of Energy committed to reduce the costs of solar energy by 75% to \$0.06 per kilowatt-hour for utility-scale PV solar power by 2020 and achieved it 3 years ahead of schedule. It had made considerable progress to make solar power cost-competitive with fossil fuels without subsidies, by supporting the development of more efficient solar cells and cost-effective manufacturing process. In 2016, US Energy Department announced new goals for 2030 to make solar one of the least expensive sources of energy generation. The Levelized Cost Of Energy (LCOE) was decided to be cut by an additional 50% to \$0.03 per kWh for utility-scale and \$0.05 per kWh for CSP power plants. The goals also included to address and resolve grid integration challenges and key market barriers for solar adoption (SunShot 2030 n.d.).

To make solar more affordable, some of the costs, such as getting permits, connecting a solar system to the power grid, and other similar expenses, also need to be adjusted. Once Battery Electric Vehicles (BEVs) are integrated into the grid using emerging integration technology, the personal vehicles will be able to use solar energy

to support the transmission and distribution of electrical power.

Summary and Conclusion

Global energy demand is growing at a fast pace. The climate change and adverse health effects of fossil fuel have made consumers, the scientific community and industry consider renewable energy a sustainable and clean alternative energy option. Among other renewable energies, solar energy is increasingly becoming the most economical option for meeting global electricity, thermal, and other power need. This new industry is also expected to generate substantial economic activities and job opportunities in every sector from the production of solar energy, electricity generation, heating and cooling systems, transportation, and more (Union of Concerned Scientists 2009).

Asian countries such as China and India are investing heavily to meet the fast growth of their energy need. The United States has made significant progress in reducing the cost of solar energy to make it competitive with coal and committed to making it less expensive than fossil fuel in the coming years. The solar energy industry is still comparatively young, and there is tremendous economic opportunity for the countries that invent, manufacture, and export clean energy technologies.

Sovereign Wealth Funds

Laxmi Remer
CBS Cologne Business School, Cologne,
Germany

Synonyms

Country investment funds; Country wealth fund;
State governed fund

Definition

A sovereign wealth fund (SWF) is a government-owned investment fund principally used to benefit the economy and citizens of a country. This fund, which comes from the country's central bank reserves, is made of sums of money accumulated over time. Such sums of money are simply income from many sources, such as, among others, budget and trade surpluses, revenues from exports of natural resources, privatizations or official foreign currency transactions, etc. Most often these investments are more tolerant towards risk, in that they tend to prefer return over liquidity. They are usually overseas long-term holdings in foreign exchange assets.

Every country decides for itself the objectives of the SWF and these tend to evolve over time. According to the Sovereign Wealth Fund Institute, a nonprofit organization, the SWFs are traditionally classified into five types as:

- Stabilization funds
- Savings or future generations funds
- Pension reserve funds
- Reserve investment funds
- Strategic development sovereign wealth funds

The names of the SWFs implicitly outline their respective objectives. Countries could have multiple objectives such as stabilization/savings as seen in Azerbaijan, Botswana, Trinidad and Tobago, and Norway or stabilization/saving/development as seen in Kazakhstan (Al-Hassan et al. 2013). On a side note, SWFs may also help avoiding the phenomenon of "Dutch disease." This is the case where the economic success in one sector in a country leads to the decline in other sectors in the said country. This is because the sector which is successful experiences increased demand leading to increased revenues including foreign currency inflows. This in turn causes the said country's currency to appreciate (i.e., become expensive relative to other currencies), which in turn leads to exports of the said country becoming expensive and therefore leading into falling export demands in other sectors.

Some countries have created SWFs to diversify their revenue streams. For example, the United Arab Emirates relies on oil exports for its wealth. Therefore, it devotes a portion of its reserves to an SWF that invests in diversified assets which creates stability.

SWFs are very important in that they allow countries to manage their respective risks in a timely and efficient manner.

Brief History

Some of the earliest SWFs originated in the United States in the nineteenth century to fund public services (Firzli and Franzel 2014). These were however only state funds. SWF for a sovereign state originated in the Middle East to invest the excess oil revenues starting around 1950s. The Kuwait Investment Authority is considered to be the first SWF and was established in 1953. It is however only since the 2000s that SWFs have become increasingly prominent with increasing oil prices and sustained growth in the Asian economies.

The total assets under management by SWFs have been growing and their holdings are estimated to be between 3 and 5 trillion US dollars (IMF 2012). According to the World Economic Forum, as of 2018, the UAE's fund was worth about US\$683 billion. The Forum also finds that Norway's SWF, the largest in the world, has exceeded US\$1 trillion since 2017.

The sheer size and investment capacity of such SWFs make them quite powerful and often very useful to recipient countries. Over 30% of the funding to rescue financial institutions from the financial crises of 2007–2008 is supposed to have come from Asian and Arab SWFs, according to Ben Bernanke, ex-Chair of the Federal Reserve of the United States, as quoted in the Financial Times (Woertz 2008).

Some Examples of the Biggest SWFs

Norway's SWF, with roughly over US\$1 Trillion under management as of 2019, is considered to be the world's largest SWF.

The Chinese SWF, namely, China Investment Corporation has, as of 2018, about US\$940 billion under management.

The United Arab Emirates SWF, namely, Abu Dhabi Investment Authority has, as of 2019, about US\$800 billion under management.

Pertinent CSR Issues

SWFs which have been traditionally long-term passive investors have been welcomed by many countries. However, more and more SWFs now seek to diversify and are investing with hedge funds and private equity. Moreover, most of the funds, apart from the Norwegian one, do not disclose their holdings nor their corporate governance structures and practices, making them dangerously opaque. This facet combined by the exceedingly large sums of money at their disposal creates some element of risk.

One of the additional and commensurate concerns is that perhaps SWFs could have some political influence. The financial clout and the intransparency of the funds fueled by their supranational status have in the past created situations of tension causing legislative changes. For example, in 2006, a British firm named P&O was taken over by Dubai Ports World (DPW), a state-owned UAE company. P&O held management contracts of six major ports in the United States, which now belonged to DPW. This business deal very soon took on the form of national security with many political figures arguing that such a deal would compromise port security. This particular incident, among other similar concerns, also led to passing of the Foreign Investment and National Security Act 2007 in the United States whereby scrutiny increased considerably in the context of investments made by foreign governments or SWFs. European governments have long been wary of SWFs given the nondisclosure policies of the latter on their investments. This has consequently led to many more demands for more transparency in both terms of objectives and the content of the portfolio investments of SWFs.

In the context of CSR therefore, SWFs currently fall considerably short of the required mark given their governance structures and stakeholder transparency issues.

Speciesism

Dyann Ross
School of Social Science, University of the
Sunshine Coast, Sippy Downs, QLD, Australia

Synonyms

[Abuse of non-human rights](#); [Anthropocentrism](#); [Discrimination](#); [Objectifying of species](#); [Securitization of nature](#); [Trans-species injustice](#)

Definition

Speciesism, also called anthropocentrism, refers to the superiority of the human species and their control over non-human animals. Speciesism is a form of discrimination that has been perpetuated throughout the history of human and non-human animal relationships. Discrimination are actions which cause harm based on unfair social practices such as marginalization and stereotyping. The result is that non-human animals are treated as objects. This leads to a culture where it is acceptable to violate the basic rights of non-human animals. The specific nature of speciesism is influenced by cultural and economic practices where there are differences in how domestic animals and pets are regarded, compared with farm animals and wild animals. Human's ability to live and sustain life on the planet is intricately interrelated with non-human animal's ability to survive and flourish.

The human-centered concept of social justice needs to be extended to include the idea of trans-species social justice where all species are equally valued beings. Further, the idea of ecocentrism locates an ethical concern for all species with an inseparable valuing of the intrinsic worth of all sentient beings, including Mother Earth as a living being. This ethical stance provides a compelling values-based approach for sustainability managers and activists to challenge environmental and social harm by large-scale resource extraction industries and agribusinesses.

Introduction

There is a continuing loss of non-human animal diversity, including species extinction, across the full spectrum of wild animals at a global level. Further, many national economies are reliant on job and wealth creation from the use and exploitation of non-human animals. For example, after years of severe drought in rural and remote Australia in the summer of 2019, a disaster on top of disaster occurred when the first signs of welcome rainfall turned to tragedy. Extreme flooding resulted in the death of hundreds of thousands of

cattle and sheep and the largely unrecognized loss of wildlife in the media.

These catastrophic events indicate the unsustainability of current trajectories of capitalist development and the interrelated wicked problem of climate change. Unsustainability can be understood as an indicator of lack of social, economic, and environmental justice and as a lack of species justice. Large-scale agribusinesses are known to deplete landscapes and use non-human animals for human consumption and wealth accumulation by the elites of society. Gina Rinehart is Australia's wealthiest woman with an estimated net worth of 21.5 billion US dollars. She earns 1 million dollars every 30 minutes from mining and more recently from large-scale farming of cattle.

A trans-species social justice coupled with a commitment to ecological justice is premised on the capacities of love and non-violence in relationship with all species and the living planet. Non-violence refers to the non-forcing of the other beings and involves seeking to engage them as an invitation where there is a constant awareness to the nonverbal and other behaviors of the animal that may be signalling unease or unwillingness. Speciesism is underpinned by a dualism between humans and non-humans. This dualism is premised on the western idea of nature as a resource for human ends and its instrumental use rather than being intrinsically worthy of respect (Plumwood 2000).

The discourses which reinforce this dualism can be subtle and part of contradictory stances by high-profile, pro-animal rights groups. For example, the Royal Society for the Prevention of Cruelty to Animals (RSPCA) is a well-known and highly respected organization. It promotes the five freedoms of animals, namely, freedom from hunger and thirst; discomfort; pain, injury, or disease; fear and distress; and freedom to express normal behavior by providing sufficient space, proper facilities, and company of the animal's own kind. At the same time, it maintains a dominant discourse in some of its language of humane killing when referring to farm animals who are called livestock. Activists against harm to non-human animals can make important contributions to animal welfare and safety – for example, campaigns against live sheep and cattle exports in Australia

which is also supported by the RSPCA. However, Francione and Charlton's (2013) abolitionist approach is against the animal welfare rights approach and argues against any use of non-human animals. They promote a number of principles to achieve this end, including the right of all sentient beings to not be the property of others and veganism as the moral baseline of animal's freedom and equality. Crucially, abolitionists recognize the principle of non-violence as a core principle of the animal rights movement.

At a global level, there is a similar tendency to place human's rights and interests above the rights and interests of the planet as a living entity even though the aim is the opposite. For example, the International Year of Planet Earth in 2008 was followed by the United Nations passing a resolution in 2009 recognizing that the Earth is vital for human's continued existence. Nevertheless, such important and necessary international statements still value the environment and all sentient beings in terms of their importance to humans. This leaves open the door for some nations and corporations to maintain control over natural resources for their own benefit at the expense of ecological and human well-being. White (2017) describes this commodification of non-human sentient beings as the securitization of nature which is the opposite to environmental security. Environmental security refers to the protection of living ecosystems for the public good, not for the elites of society.

Ecocentrism challenges speciesism and requires humans to act with awareness of and respect toward all living beings and ecosystems (White 2018). Indigenous cultures consider humans as the custodians of the environment, and they also believe rivers, mountains, and the planet are living entities. The Creative Spirits website (2019) explains that "Aboriginal spirituality is deeply linked to the land which 'owns' Aboriginal people. All objects are living and share the same soul or spirit Aboriginal people share." They acknowledge Mudrooroo who writes that "our spirituality is a oneness and an interconnectedness with all that lives and breathes, even with all that does not live or breathe" (cited by Creative Spirits 2019, n.p.).

Western cultures and dominant human-centered discourses have given some credence to the planetary ecosystems equal right to exist for its own intrinsic value. For example, despite being heavily critiqued on scientific grounds, the Gaia hypothesis (Lovelock 1979) is based on the recognition of planet Earth as a dynamic, living, and intricately interlinked system of entities that is self-regulating and self-sustaining. The full implication of speciesism and other forms of discrimination in unequal, exploitative economic and political systems such as capitalism and colonialism is the threat now posed to this self-sustaining living planet.

Deep ecology has made an important contribution to the issues of environmental unsustainability, and these ideas have been integral to the international environmental movement. A film by Macy (2019) explains that Mother Earth is being subjected to the onslaught of an industrial growth society. She explains that human evolution is at a point of great turning based on the recognition that humans belong to the planet like cells in a living body. Her classic book *World as Lover, World as Self* (2003) has been influential in what is becoming the greatest social movement in history based on a growing awareness of the interdependency of all living beings and the need to protect the planet.

The Sustainability Issue

Capitalism, colonialism, and neoliberalism are interlinked systems of economics and politics that promote so-called free trade, competition, and individualism. This is expressed as a light-touch regulatory approach of pro-development national governments and a paring back of welfare and other universalist social programs. Further, the dominant value of anthropocentrism undercuts an inclusive and just moral regard for non-human animals, other sentient beings, and Mother Earth. These combined dominant power dynamics wreak havoc on the rights of minority groups such as Indigenous People, people seeking asylum, and non-human species. A minority social group's value is directly related to their use value in relation to the wealth creating logic of capital. The use and killing of non-human animals are morally justified

as part of the human condition and the capitalist mode of production. Production, including the farming, marketing, and slaughtering of non-human animals, is out of sight and advertising is sanitized. This has the combined effect of separating humans from the abuse and killing of non-human animals for human use.

Research shows that humans who work in abattoirs that slaughter non-human animals tend to be immigrants and refugees with few other job prospects. Abattoir workers experience high levels of mental illness and trauma directly related to the work. Research also shows that one of the main causes of a warming planet relates to the production of cattle for human consumption. This is partly due to the de-afforestation and unsustainable land management practices that leave large tracks of landscape susceptible to extreme weather conditions and animal loss. In turn, some concerning illnesses such as mad cow disease are directly related to the mass production of animals for human consumption.

One issue within this complexity of issues is the unequal power of the owners of multinational entities in the resource extraction industries and large-scale agribusinesses. This maintains a status quo in the global situation of increasing ecological conflicts. These types of conflict are directly related to economic growth that uses the environment. Internationally, the unsustainability and socio-environmental harm caused by this type of development are well recognized. The inequality that occurs in the global system of production and trade is normalized and taken as a necessary evil. The effect is a normalizing of the plundering of the planet linked to increasingly repressive measures against protesters and leaders of environmental resistance movements. In 2016 four people were murdered every week trying to protect their land from mining, forestry, and agricultural businesses.

White (2009) argues that environmental harm, including harm to non-human animals, is a state crime as the state has failed to ensure the rights and safety of its people and the sustainability of industries that use natural resources. This is complicated by the dynamics of globalization where the pursuit of multinational corporation's interests has overtaken the legal structures of nation-states

that should protect the human and land rights of its people.

Summary: Ecocentrism as a Unifying Ethic for Sustainable Development

The human-centered concept of social justice needs to be extended to include the idea of trans-species social justice where all species are equally valued beings. Further, the idea of ecocentrism locates an ethical concern for all species with an inseparable valuing of the intrinsic worth of all sentient beings, including Mother Earth as a living being. This ethical stance provides a compelling values-based approach for sustainability managers and activists to challenge environmental and social harm by large-scale resource extraction industries and agribusinesses.

The adoption of ecocentric ethics in all matters relating to wealth creation, and the economic base of society, can hold traction with the effects of unsustainable and unjust business practices. An ethical literacy is needed in matters of ecological conflict that refuses to allow any impacted stakeholder group to be sacrificed for the greater good or harmed as a trade-off for jobs or business profits. Environmental victims turned activists need to be protected from violent backlashes when they are acting for trans-species justice and for the sustainability of Mother Earth.

Definition

Spirituality is the journey to find one's own self and its interconnectedness with the world at large. It's a search for meaning that goes beyond material well-being. Spirituality is the journey which focuses on basic, deep-rooted human values and its relationship with a universal source, power, or divinity. Management decision-making considerably affects the life and fate of people around us, natural ecosystems, and future generations in other words stakeholders at large. The well-being of these stakeholders requires authentic care, which can develop only when people, in the management decision-making, experience oneness with others and with the universal source of creation. Thus spirituality in management perspective embraces the spiritual values of integrity, honesty, accountability, quality, cooperation, service, intuition, trustworthiness, respect, justice, and service in a business context.

Introduction

Over a decade or so, there has been a growing interest in the role of spirituality within traditional management discourse and research. According to Kolodinsky et al. (2010), spirituality is “an intrapersonal and metaphysical relationship with a higher power or transcendent force which provides motivation, purpose, and a sense of
